AMERICAN MEDICAL ASSOCIATION, CHICAGO, 1941

OFFICERS OF THE AMERICAN MEDICAL ASSOCIATION—1941-1942

HEADQUARTERS OF THE ASSOCIATION, 535 N. DEARBORN ST., CHICAGO

GENERAL OFFICERS

PRESIDENT—FRANK H. LAHEY	Boston
PRESIDENT-ELECT—FRED W. RANKIN	Lexington, Ky
VICE PRESIDENT—CHARLES A. DUKES *	Oakland, Calif
SECRETARY AND GENERAL MANAGER—OLIN WEST	Chicago
TREASURER—HERMAN L. KRETSCHMER	Chicago
SPEAKER, HOUSE OF DELEGATES—H. H. SHOULDERS	Nashville, Tenn
VICE SPEAKER, HOUSE OF DELEGATES—R. W. FOUTS	Omaha
EDITOR—MORRIS FISHBKIN	Chicago
BUSINESS MANAGER—WILL C. BRAUN	Chicago

BOARD OF TRUSTEES

Arthur W. Booth, Chairman	Elmira, N. Y., 1942
R. L. Sensenich	South Bend, Ind., 1942
Ernest E. Irons, Secretary	Chicago, 1943
William F. Brasch	Rochester, Minn., 1943
Roger I. Lee	Boston, 1944
E. L. Henderson	Louisville, Ky., 1944
Ralph A. Fenton	Portland, Ore., 1945
James R. Bloss	Huntington, W. Va., 1945
Charles W. Roberts	Atlanta, Ga., 1946

JUDICIAL COUNCIL

Holman Taylor	Fort Worth, Texas, 1942
John H. O'Shea	Spokane, Wash., 1943
Edward R. Cunniffe	New York, 1944
G. E. Hollansbee, Chairman	Cleveland, 1945
Walter F. Donaldson	Pittsburgh, 1946
Olin West, Secretary, ex officio	Chicago

COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

Reginald Fitz	Boston, 1942
Russell L. Hyden	Cleveland, 1943
Charles Gordon Heyd	New York, 1944
H. G. Weiskotten, Secretary	Chicago, 1945

R. I. Wilbur, Chairman	Stanford University, Calif., 1946
John H. Musser	New Orleans, 1947
Harvey B. Stone	Baltimore, 1948

COUNCIL ON SCIENTIFIC ASSEMBLY

Clyde I. Cummer	Cleveland, 1942
James E. Paulin, Chairman	Atlanta, Ga., 1943
J. Gurney Taylor	Milwaukee, 1944
A. A. Walker	Birmingham, Ala., 1945
Frederick A. Collier	Ann Arbor, Mich., 1946

AND EX OFFICIO

The President Elect, the Editor and the Secretary of the Association	
--	--

COUNCIL ON PHARMACY AND CHEMISTRY

(Standing Committee of Board of Trustees)	
R. A. Hatcher	New York, 1943
H. N. Cole	Cleveland, 1943
Stuart Mudd	Philadelphia, 1943
J. Howard Brown	Baltimore, 1944

James P. Ierke	Washington, D. C., 1944
David P. Barr	New York, 1944
Morris Fishbein	Chicago, 1945
G. W. McCoy	New Orleans, 1945
Perrin H. Long	Baltimore, 1945
Elmer M. Nelson	Washington, D. C., 1945
Torald Sollmann, Chairman	Cleveland, 1946
W. C. Rose	Urbana, Ill., 1946
E. L. Sebringhaus	Madison, Wis., 1946
E. M. K. Geiling	Chicago, 1947
S. W. Palmer	New York, 1947
W. W. Chusen	Rochester, N. Y., 1947
Austin E. Smith, Acting Secretary	Chicago

COUNCIL ON PHYSICAL THERAPY

(Standing Committee of Board of Trustees)

W. E. Garrey	Nashville, Tenn., 1943
W. W. Coblenz	Washington, D. C., 1943
John S. Coulter	Chicago, 1943
Ben J. Carey	Milwaukee, 1944
Frank R. Ober	Boston, 1944
Frank D. Dickson	Kansas City, Mo., 1944
A. U. Desjardins	Rochester, Minn., 1945
H. B. Williams	New York, 1945
Frank H. Krusen	Rochester, Minn., 1945
Anthony C. Cipollaro	New York, 1946
George M. Piersol	Philadelphia, 1946
M. A. Bowie	Bryn Mawr, Pa., 1946
Morris Fishbein, ex officio	Chicago
Howard A. Carter, Secretary	Chicago

COUNCIL ON FOODS AND NUTRITION

(Standing Committee of Board of Trustees)

Lydia J. Roberts	Chicago, 1943
George R. Cowgill	New Haven Conn., 1943
C. S. Iadd	Washington, D. C., 1944
Tom D. Spies	Cincinnati, 1944
Irvine McQuarrie	Minneapolis, 1945
Morris Fishbein	Chicago, 1945
R. M. Wilder	Rochester, Minn., 1946
Howard B. Lewis	Ann Arbor, Mich., 1946
J. S. McLester, Chairman	
	Birmingham Ala., 1946
Philip C. Jeans	Iowa City, 1947
C. A. Elvehjem	Madison, Wis., 1947
Franklin C. Bing, Secretary	Chicago

COUNCIL ON INDUSTRIAL HEALTH

(Standing Committee of Board of Trustees)

I. D. Bristol	New York, 1943
Stanley J. Seeger, Chairman	
	Texas, 1943
Philip Drinker	Boston, 1943
Harvey Bartle	Philadelphia, 1944
Leroy U. Gardner	Saratoga Lake, N. Y., 1944
A. J. Lanza	New York, 1944
Robert T. Legge	Berkeley, Calif., 1944
Warren F. Draper	Washington, D. C., 1945
Henry H. Kessler	Newark, N. J., 1945
C. D. Selby	Detroit, 1945
Raymond Hussey	Baltimore, 1945
C. M. Peterson, Secretary	Chicago

COMMITTEE ON SCIENTIFIC EXHIBIT

Roger I. Lee, Chairman	Boston
E. L. Henderson	Louisville, Ky
Ralph A. Fenton	Portland, Ore
Thomas G. Hull, Director	Chicago

ADVISORY COMMITTEE

D. Chester Brown	Danbury, Conn

CARCINOMATOUS GASTRIC ULCER

MISLEADING RESULTS OF MEDICAL THERAPY

GEORGE B. EUSTERMAN, M.D.

ROCHESTER, MINN.

It is apparent that the rank and file of the medical profession are becoming increasingly conscious of the fact that small, circumscribed, innocent looking ulcerous gastric lesions may actually be carcinomatous. Progress in our knowledge in this respect so far is due largely to disclosures by roentgenoscopy and the unexpected results of microscopic examination of presumably benign excised lesions or lesions in resected portions of the stomach.

From time to time a patient who has what is proved eventually to be a malignant circumscribed gastric lesion undergoes treatment for the usual chronic benign ulcer. There are extenuating reasons for this, because an ulcerating form of carcinoma may be indistinguishable from a benign one on the basis of the usual criteria. Moreover, the patient may refuse immediate operation irrespective of the probable nature of the lesion. Finally, the risk of the operation under certain circumstances may be greater on first blush than the risk of death from carcinoma. While any unnecessary delay in the proper treatment of a malignant growth always is to be deplored, there is the advantage of learning something of the behavior of such lesions under an intensive medical regimen.

While a considerable literature bearing on the differential diagnosis of carcinomatous and benign ulceration has accumulated, insufficient stress has been placed on the diagnostic significance of the response to medical treatment. In my judgment the roentgenologist and the surgeon have been particularly remiss in this respect. The circumspect physician is today as much concerned with the degree of demonstrable anatomic change in an ulcer undergoing treatment as with the symptomatic improvement. In fact, he has not placed too much credence on the latter for some years because he realizes that disturbances arising from gastric carcinomas of all types can be relieved temporarily in a disconcertingly large number. He may also be aware of the fact that in an average of almost a third of all verified cases of gastric carcinoma an ulcer type of complaint may be the initial or predominating one. And with much justification he regards the complete and fairly prompt disappearance of all roentgenographic evidence of a lesion and of the symptoms as trustworthy and almost absolute proof of benignancy.

However, before any hard and fast rules can be laid down, authoritative observations must be made on a number of histologically verified cases sufficiently large to be of statistical value. This applies to the effect of adequate treatment, not only on benign but on carcinomatous lesions as well. With respect to the former, we are treading on more familiar ground. Uncomplicated subacute ulcers and chronic ulcers not of too long duration usually heal without difficulty, although the latter may recur eventually. But incomplete healing of a benign ulcer due to one of the various well recognized factors obviously can give rise to difficulties in differential diagnosis. Suffice it to say that the failure of the niche to disappear completely after an adequate course of intensive treatment does not imply necessarily that the lesion is carcinomatous. Infrequently even an uncomplicated ulcer may undergo complete healing, with persistence of a niche, as shown by Unger and Poppel.¹ That this phenomenon does not occur oftener has frequently puzzled me when recalling that the bulbar deformity caused by chronic duodenal ulcers will persist almost invariably after such ulcers are healed completely and permanently. Undoubtedly the most reliable evidence as to the extent of healing of a gastric lesion is afforded by the gastroscopic examination. Our experience in this respect supports the contentions of Templeton and Schindler² and others that an ulcer still may be active and unhealed even though there is complete disappearance of the niche from a roentgenologic point of view.

Judging from past published reports, the large majority of carcinomatous ulcers or ulcerating carcinomas decrease little in size, if at all, under the influence of medical treatment. Some actually have been known to increase in size. Whether this is true of the earliest preinvasive types of carcinoma, so-called carcinoma *in situ*, especially those associated with hydrochloric acid in the gastric contents, remains to be seen. Taylor,³ on the basis of repeated gastroscopic observations, expressed the conviction that the failure of an ulcer to change at all after three weeks of intensive treatment in the hospital is sufficient evidence of malignancy. On the other hand, if on the second examination an ulcer shows signs of uniform healing, he took the attitude that malignancy can be definitely excluded. Gutmann⁴ expressed the opinion that any lesion in which there is a persistence of clinical and radiologic signs after six weeks of treatment is suggestive of carcinoma. He regarded the presence of cancer as practically certain when

Read before the Section on Gastro-Enterology and Proctology at the Ninety-Second Annual Session of the American Medical Association, Cleveland, June 6, 1941.

there are a persistence of clinical symptoms and the increase of roentgenologic signs, and as definite for carcinoma disappearance of the clinical symptoms with progressive increase of the roentgenologic signs. Mallory⁵ made observations on 4 cases of early ulcerous gastric carcinoma in which there was definite diminution in the size of the crater. In the first case, in which there was an ulcer in the prepyloric region, the niche itself had disappeared completely on roentgenologic examination after eight weeks of treatment.

The subject is one of considerable significance because a fifth of all the carcinomatous lesions removed at the Mayo Clinic in recent years may be within the size range of benign ulcer (4 cm. or less in diameter). As only 6.5 per cent were small (2.5 cm. or less) MacCarty⁶ felt that gastric carcinoma was not being diagnosed early.

While repeated experience in the past has taught me that a carcinomatous form of ulcer may undergo little objective change, if any, while under treatment, the improvement at other times, especially during the earlier

Fig. 1 (case 3).—a, large "penetrating" gastric ulcer, posterior wall, near lesser curvature, above incisura angularis; b, shallow ulcerating lesion at the original site; c, shallow ulcer, 2 cm. in diameter, at the original site.

stages of the lesion, can be so striking as to be misleading. The following cases, of which case 1⁷ and case 3⁸ have been reported previously, with illustrations, are indicative of this:

REPORT OF CASES

CASE 1.—A white man aged 27, who entered the Mayo Clinic on Nov. 10, 1931, for five years previously, usually late in the summer and in early spring, had experienced "spells" of indigestion lasting one to four months, with intervals of complete freedom. Two years prior to admission here he had had a severe attack during an exacerbation, strongly suggestive of a subacute "protected" perforation. On his own volition he drank milk at frequent intervals, and as a result there was considerable improvement. For nine months before he came under our observation the pain had been replaced by distress of the type of gaseous distention.

Physical examination and routine laboratory investigations were without incident. Concentration of free hydrochloric acid after an Ewald type of meal was 38. Roentgenologic examina-

tion, made Nov. 11, 1931, gave evidence of a perforating ulcer on the lesser curvature of the stomach, above the incisura angularis. A smaller one was also present just above that. After a course of intensive treatment for ulcer in the hospital, roentgen examination on Dec. 2, 1931, disclosed a complete disappearance of both lesions.

The patient was asked to return here for examination within three months but did not do so until Oct. 3, 1932, seven months after the time when he should have returned. In the meantime he had experienced the seasonal exacerbations as before. Relief by the taking of food or alkalis was less marked. He had lost 16 pounds (7.3 Kg.). Roentgen examination on Oct. 4, 1932 disclosed a large perforating ulcer on the lesser curvature, possibly a carcinoma, with a smaller ulcer just below it.

At operation on Oct. 13, 1932, a mass was found, the size of a fist, involving the middle and upper thirds of the stomach, with extensive posterior infiltration. Regional lymph nodes were enlarged. There seemed to be a 90 per cent chance that the growth was a carcinoma. The abdomen was closed after exploration only. Roentgen therapy was instituted. Progressive decline followed, with pain, ileus, vomiting and eventually signs of generalized peritonitis. The patient died on Feb. 4, 1933. At necropsy a large, ulcerating carcinoma of the stomach, with generalized peritonitis, was found.

Features of interest are the comparative youth of the patient, the association of a painful, chronic, perforated benign ulcer with a carcinoma in situ, and complete, even though temporary, disappearance of both lesions. from a roentgenographic standpoint, after treatment.

CASE 2.—A white man aged 30, who entered the Mayo Clinic on Feb. 6, 1940, had always had a "weak stomach" and was an "easy vomiter." His mother "suffered from a peptic ulcer" for a number of years but died of cancer of the stomach at the age of 45 years. Since 1934 the patient had had ulcer-like manifestations, much belching and resulting gaseous distention. In June 1935 an ulcer, apparently on the lesser curvature in the prepyloric region, was found on roentgen examination. After three weeks of intensive treatment the lesion had disappeared completely on reexamination. In October 1936 there was a recurrence of the original symptoms, characterized by epigastric pain appearing one hour after each meal, which appeared to be relieved more or less completely by food and alkalis. Roentgen examination in December 1936 disclosed only antral spasm. Because of incomplete relief by treatment, operation was advised in March 1937. On exploration of the stomach an ulcer was not found but pyloroplasty was done.

Since this operation the patient has been free of his former ulcer-like discomfort, but for a year and a half prior to entering the clinic he had had much gaseous distention, nausea and vomiting, the latter sometimes of retention character, and a loss of weight. In February 1939 analysis of gastric contents after stimulation with histamine revealed a total acidity of 106 and free hydrochloric acid of 88 clinical units.

The positive findings obtained on admission were moderate anemia, alkalemia and an ulcerating lesion in the distal third of the stomach with pyloric obstruction on roentgen examination. An analysis of 350 cc. of vomited material disclosed considerable altered blood and on titration free hydrochloric acid of 30 units. At operation on Feb. 10, 1940 an annular ulcerated colloid adenocarcinoma (8 by 7 by 2 cm.), grade 4 (Broders' method), beginning just above the pylorus and completely encircling it, was removed. The overlying serosa and regional lymph nodes were involved.

The prepyloric location of the lesion in spite of the comparative youth of the patient and the history of gastric carcinoma in the patient's mother were significant. One can only speculate as to what relation the original lesion, which disappeared under treatment, bore to the ultimate extensive one.

CASE 3.—A white woman aged 44, married, entered the hospital directly on July 23, 1939 because of recent hematemesis of moderate severity. For a period of four years the patient

8. Eusterman, G. B.: Small Carcinomatous Gastric Lesions Simulating Chronic Benign Ulcer: Present Status of Differential Diagnosis and Treatment, *Minnesota Med.* 23: 703-709 (Oct.) 1940.

had had indigestion, remittent in course but progressive in severity. This was characterized by a low retrosternal pain appearing a half to one hour after each meal, often extending laterally to the left hypochondrium or posteriorly to the left subscapular region. The duration of the pain was usually an hour or two. Ingestion of warm fluids or alkaline mixtures, or induced vomiting, afforded relief rather uniformly. Roentgenoscopy in December 1937 at the patient's home by a competent roentgenologist disclosed an ulcer "quite high up in the stomach and on the posterior wall." After this examination the patient entered the hospital in her home town and submitted to treatment for ulcer for a period of five weeks. Then she enjoyed good health until March 1939, at which time there was a recurrence of her original symptoms in aggravated form, precipitated by emotional and physical stress. Four days prior to admission here the roentgenologist again confirmed the presence of the original lesion without any significant changes. The physical examination and routine laboratory investigations were without special incident. The positive findings on July 29, 1939 were moderate low grade hypochromic microcytic anemia and the presence of a large "penetrating" ulcer on the posterior wall of the stomach near the lesser curvature above the incisura angularis (fig. 1*a*). Analysis of the gastric contents (Ewald) disclosed a total acidity of 46 and free hydrochloric acid of 26 clinical units, as well as the presence of considerable altered blood. The total aspirated contents measured 160 cc.

Intensive treatment for ulcer was instituted promptly. This treatment, however, was interrupted for two weeks during August because of an intervening obscure illness characterized

ing home. Roentgenoscopy at this time revealed a small shallow defect with evidence of considerable scarring and puckering of the contiguous mucosa. On gastroscopy a small ulcer on the posterior wall, just above the incisura angularis, corresponding to the site of the lesion on roentgen examination, was seen. The margin of the ulcer appeared to be quite edematous but the lesion in its major aspects appeared to be benign.

Fig. 3 (case 3).—Ulcerating adenocarcinoma, for the most part, in situ. However, there is invasion of submucosa at one point. The muscle plane is intact. (Broders.)

After another two week period of treatment, roentgen examination on Dec. 23, 1939 disclosed a shallow ulcerating lesion at the original site (fig. 1*b*). A second gastroscopy on Jan. 9, 1940 did not reveal any evidence of ulceration at this time. The gastric mucosa was scarred and puckered and there was an "area of gastritis" at the site of the previous lesion. Four days later roentgen examination revealed a shallow defect about 2 cm. in diameter at the site of the original lesion, with deformity of the surrounding gastric rugae.

On April 12, 1940 the patient again reported, as requested, for examination. She had experienced a mild recurrence of trouble for several days during the previous month as the result of emotional strain. Roentgen examination the following day disclosed findings identical with those at the last examination in January (fig. 1*c*), but on gastroscopy there was present a fairly deep ulcerating lesion the crater of which was about 1 cm. in diameter. The ulcer was irregular in contour, the border had a rolled appearance and the base was covered with a shaggy exudate. The mucosa near the incisura angularis was decidedly edematous, and several submucosal hemorrhages were seen in this area. On April 18, 1940 partial gastrectomy of the posterior Polya type was performed by Dr. Walters. The lesion proved to be an ulcerating adenocarcinoma (2 by 1.5 cm.), grade 3 (figs 2 and 3). It had invaded the submucosa but had not involved the musculature. There were associated gastritis and very early glandular involvement. A good recovery was made and the patient was enjoying good health at the time this paper was written.

Note again the evidence of almost complete healing, both from a roentgenologic and from a gastroscopic point of view. The location of the lesion on the posterior wall is significant. Can one attribute the symptoms present for a total of five years to carcinoma, or is this an example of the malignant transformation of a benign ulcer? While absolute proof is lacking, I am of the opinion that the lesion was carcinomatous from the outset, as the muscle plane was intact.

CASE 4.—A man aged 68 came to the Mayo Clinic on March 21, 1938 because of stomach trouble. In 1923 and 1928 he had experienced brief periods of gastric distress coincident with unusual nervous and physical strain. This distress, which was characterized by gas and hunger pain, was situated in the epigastrium and appeared about two hours after each meal. On relief from occupational stress the symptoms promptly dis-

Fig. 2 (case 3).—Grade 3 adenocarcinoma in which the cells have spherical and irregular hyperchromatic nuclei, with a little tendency to acinar formation.

by fever, headache, peripheral neuritis, purpura, nausea, vomiting, icterus and leukopenia. The guaiac reaction for occult blood in the feces was intermittently positive and the benzidine reaction was usually positive throughout the period in the hospital. Roentgen examinations on Aug. 6 and Sept. 1, 1939 showed that the lesion had decreased considerably in size.

At our request the patient returned here for another examination on Dec. 8, 1939, although she not only had been free from symptoms but had gained 8 pounds (3.6 Kg.) since return-

appeared. The present illness began about three months prior to the patient's admission to the clinic, during the Christmas holiday (December 1937). Epigastric distress appeared about one hour after each meal and persisted for several hours. Alkalis or milk afforded relief. There was no impairment of weight, appetite or strength. In February 1938 a gastric ulcer was diagnosed after roentgen examination. Ambulant treatment for ulcer was instituted promptly and the symptoms disappeared. Because there was not a proportionate improvement in the roentgenographic appearance of the lesion, the patient was referred to the clinic for an opinion.

The general physical examination gave satisfactory results. The patient was short, stocky and well nourished. Analysis of gastric contents after an Ewald meal revealed a total acidity of 32 clinical units and free hydrochloric acid 20. The total contents removed measured 125 cc. Roentgen examination on March 28, 1938 revealed a shallow ulcer on the lesser curvature just below the incisura angularis. The presence of the ulcer was confirmed by gastroscopy three days later. The gastroscopic appearance was that of a small benign lesion on the lesser curvature and anterior wall distal to the incisura angularis.

The patient was hospitalized and underwent intensive treatment for more than a month. Roentgen examination was repeated April 18, 1938, but this failed to disclose any sign of the ulcer. On gastroscopy, July 7, 1938, the original ulcer had disappeared completely. Roentgen examination on Sept. 14, 1938 again revealed normal conditions. The patient had experienced none of his previous distress in the meantime. However, he was asked to return periodically for reexamination on account of his advanced age and the recent onset of the symptoms. On Jan. 17, 1939 there was roentgenographic evidence of a recurrence of the ulcerating lesion. Two days later gastroscopy revealed the lesion as depicted on the film. It was situated at the original site and appeared to be fairly well circumscribed, somewhat indurated and 2 cm. in diameter. On June 25, 1939 partial gastrectomy was performed.

The pathologic findings were as follows: An ulcerating colloid carcinoma, grade 3, measuring 2 by 2 by 1 cm., was situated on the anterior wall and lesser curvature of the stomach, 3 cm. above the pyloric ring. The serosal surface of the stomach immediately underlying the ulcer showed carcinomatous lymphangitis. No involvement of the lymph nodes was found.

The patient was examined again on Feb. 13, 1940 and appeared to be in excellent health. At the present writing he has no disturbances of any kind and appears to be enjoying good health.

This is a most striking example of the disappearance of all symptoms and signs of early gastric carcinoma from both the roentgenologic and gastroscopic point of view after treatment. It was largely because of the late appearance of the lesion at an advanced age that we felt close surveillance necessary in the ultimate interests of the patient. Such apprehension was justified by the course of events.

That other physicians have had similar experiences to our own is attested by the following case:

CASE 5.—A white man aged 59, who entered the Mayo Clinic Feb. 3, 1941, for fifteen years had experienced intermittently "mild heartburn" appearing an hour and a half after meals, which was relieved regularly by sodium bicarbonate. After an attack of syncope and melena in February 1939, examination elsewhere by competent observers disclosed the presence of an ulcer with a large crater on the posterior wall of the stomach. He underwent intensive treatment, and roentgen examination in May 1939 showed that all signs of the lesion had disappeared. The patient was also entirely free from symptoms. After a brief episode of moderately severe epigastric pain, which extended posteriorly, and vomiting, in August 1940 examination disclosed that the original lesion had recurred. Under a second course of intensive treatment the ulcer gradually decreased in size so that by Nov. 1, 1940 it was barely visible on roentgen examination.

Three weeks prior to admission here the symptoms were characterized by progressive decrease in gastric capacity and appetite, without appreciable loss of weight, or pain. A burning discomfort was present when the stomach was empty.

Physical examination disclosed an extensive mass in the right portion of the epigastrium, and gastric analysis showed the presence of free hydrochloric acid. Roentgen examination disclosed the presence of an extensive defect involving the lower two thirds of the stomach. At operation on Feb. 8, 1941 a huge inoperable carcinoma involving practically the entire stomach was found. There was extragastric extension into the gastrohepatic omentum, and the growth extended upward nearly to the insertion of the esophagus.

Note the large size of the crater as well as the posterior location of the original lesion, features which not only justify a healthy suspicion of carcinoma but prompt surgical intervention.

It is apparent that gastric carcinoma not only may masquerade successfully as benign ulcer but may react to treatment in similar fashion as well. In this article I have particularly tried to avoid the highly controversial subject of the causal relation of chronic benign ulcer to carcinoma. In the light of present knowledge the problem remains an insoluble one. All types of gastric cancer are notoriously prone to ulceration, the process ranging from superficial erosion to deep crateriform formation and frequently even to the extent of causing perforation. Such process has been attributed ordinarily to infection or interference with the blood supply. As regards the stomach, the factor of peptic ulceration in the presence of free acid has been given serious consideration for years by several German observers. Their views have found a recent champion in Mallory on the basis of histologic and clinical evidence and the nature of the response to treatment. The rather prompt diminution in the size of the crater and even its actual disappearance can be attributed in all probability to two factors: first, the reparative effect of treatment on secondary peptic ulceration of cancerous tissue identical with that which obtains in benign ulcer and, second, the filling in of the base of the ulcer by cancerous tissue. The latter factor was also pointed out by Rigler.⁹ In Mallory's third case "the former ulcer crater was completely filled with carcinoma in situ."

The evidence already at our disposal seems to justify close scrutiny of all gastric lesions undergoing medical treatment, no matter how favorable the response, if the slightest suspicion of carcinoma exists. Such suspicion is especially justifiable under the following circumstances: location of the lesion in the prepyloric first inch, posterior wall or greater curvature, large size, consistent achlorhydria after stimulation with histamine, persistent or frequent recurrence of occult blood in the feces during treatment, late onset in an elderly person, and reduced gastric acidity and secretory volume estimated under basal conditions, especially in association with early pyloric obstruction. All patients submitted to treatment should undergo routine examination at intervals of three months for at least a year and at intervals of six months thereafter for an additional period of twelve to eighteen months.

CONCLUSIONS

Small ulcerating forms of gastric carcinoma not only may be clinically indistinguishable at times from chronic benign ulcer but may respond to medical treatment so

9. Rigler, L. G.: The Roentgen Diagnosis of Small Carcinomata of the Stomach, Wisconsin M. J. 34: 236-241 (April) 1935.

favorably as to give a wrong impression of their true nature. Such response seems especially characteristic of carcinoma in situ.

The real and apparent favorable reactions to treatment of early carcinomatous ulcers are attributed, respectively, to the effect of such treatment on secondary peptic ulceration of cancerous tissue and to the filling in of the base of the ulcer with the latter.

The rate and extent of healing of an ulcerous gastric lesion undergoing adequate treatment are of primary importance in differential diagnosis. However, all treated patients should be submitted to periodic reexamination irrespective of how favorable the response. Such follow-up is particularly imperative in the presence of lesions with the clinical features which have been discussed.

BLEEDING PEPTIC ULCER

CLINICAL APPRAISAL OF VARIOUS METHODS OF TREATMENT BASED ON A SERIES OF 408 CASES

HENRY A. RAFSKY, M.D.

AND

MICHAEL WEINGARTEN, M.D.

NEW YORK

The methods advocated in the treatment of massive hemorrhage from peptic ulcer have basically followed four general plans: (1) initial fasting and dietary restriction, (2) immediate feeding, (3) intubation and (4) surgery. Varied mortality percentages have been reported not only for the different methods but with the same procedures. Although these variations may be due to differences in the type of case encountered, nevertheless there is confusion as to the best therapeutic approach in bleeding peptic ulcer. The most commonly employed method has been the restricted dietetic regimen, based on the theory that an initial fasting period of variable duration followed by a diet of the Sippy type aids in healing the ulcer and prevents recurrence of bleeding by resting the stomach and neutralizing the acidity. The mortality with this method has ranged from 4.2 per cent in 94 cases¹ to 25 per cent in 191 cases.² The immediate feeding plan was first advocated in 1904 by Lenhartz,³ who gave milk and eggs from the day of admission and scraped beef on the sixth day. He claimed that anemia and depletion were more readily overcome and that recovery was more rapid. His mortality rate was 2.1 per cent in 146 cases.⁴ Andresen⁵ advised the immediate feeding of gelatin mixtures and withheld venoclyses and transfusions during the initial period. He reported a mortality of 2.5 per cent in 120 cases.⁶ LaDue⁷ treated 79 patients with Andresen's diet and had a mortality of 6.3 per cent, including 2 patients who received parenteral fluids

and succumbed. In 1933 Meulengracht⁸ advocated a liberal puréed vegetable and minced meat diet from the day of admission. His mortality rate was 2 per cent in 491 cases.⁹ In this country the mortality percentages with this method had been reported as 0 in 15 cases,¹⁰ 5.3 in 133 cases¹¹ and 8.6 in 23 cases.¹² Duodenal intubation was suggested by Einhorn¹³ in 1920. By this method he gave a liberal diet beyond the ulcer area, at times introducing the tube within six to twelve hours after admission.¹⁴ In 1925 one of us¹⁵ reported a series of 40 cases treated with duodenal alimentation without a fatality. Soper¹⁶ used a nasal retention catheter, at first lavaging the stomach and then giving duodenal feedings. Woldman¹⁷ gave a continuous colloidal aluminum hydroxide drip through a nasogastric tube inserted just beyond the cardia and permitted a bland diet by mouth. His mortality rate was 2 per cent in 144 cases. Surgical intervention has been attended by a mortality rate ranging from 5 to 30 per cent. Finsterer¹⁸ advised immediate resection in acute hemorrhage, while Gordon-Taylor,¹⁹ Allen and Welch²⁰ and Hinton²¹ advocated surgical intervention in selected cases, and Blackford and Williams²² urged prompt surgery in the older age group.

In an attempt to evaluate some of the methods employed, a series of 408 patients with bleeding peptic ulcer, treated in the various divisions of two hospitals from 1927 to April 1941, was studied. They comprised ward as well as private patients. Three hundred and forty-five were males and 63 were females. The youngest was 12 years of age and the oldest 86 years. Three were Negroes. Two hundred and seventy were under 50 years of age; of these 13 died, a mortality of 4.8 per cent. One hundred and thirty-eight patients were 50 years of age or over; of these, 23 died, a mortality of 16.6 per cent. In 18 of the 408 cases, or 4.4 per cent, hemorrhage was the sole cause of death. In 18 other cases, or 4.4 per cent, complicating diseases contributed to the fatalities. The total mortality for the series was 8.8 per cent. In table 1 the age and sex distribution and mortality have been outlined by decades.

A duodenal ulcer was demonstrated in 287 cases, a gastric ulcer in 55, both gastric and duodenal ulcers in 6, a marginal ulcer in 18, and both a marginal and a duodenal ulcer in 1. In 22 cases the radiologic examination after the hemorrhage was negative, but a sub-

and in 19 others in which further examinations were refused the previous history and the clinical course clearly indicated the presence of a peptic ulcer.

2. Thirty-nine patients were given the Meulengracht diet immediately on admission to the hospital. In 26 of these this plan could be followed without interruption. It had to be discontinued in 13, owing to a recurrence of bleeding in 7, 3 of whom died; severe pain in 3, 1 of whom had a perforation of his ulcer and died postoperatively, and severe nausea and vomiting in 3. Four of the 39 patients, or 10.3 per cent, died; of these, 2, or 5.1 per cent, died of bleeding *per se*.

3. Thirty-four patients were treated by duodenal alimentation according to Einhorn's method. The tube was inserted within twenty-four hours after admission. Small oral feedings of milk were given hourly until the tube reached the duodenum, when duodenal alimentation was instituted. One of the 34 patients, or 2.9 per cent, died of exsanguination.

Frank hematemesis alone was present in 71 cases, tarry stools alone in 160 and both hematemesis and melena in 177. Patients with only blood streaked vomitus or occult blood in the stool were not included in this series. Two hundred and eighty-three patients were seen during their first hemorrhage, 84 in the second and 25 in the third. Sixteen had four or more hemorrhages. One patient was seen in his twelfth bleeding episode. In 43 cases hemorrhage was the first symptom to appear.

The severity of the bleeding in this series was graded according to the lowest recorded hemoglobin value and red blood count in each case, grossly as indicated in table 2. Where there was overlapping of the values into two grades, the final classification was based on additional data such as the presence of restlessness, vertigo, syncope or collapse, the pulse rate, blood pressure, serum proteins and blood urea nitrogen and the amount of bleeding actually observed during the hospital stay. These criteria are a more satisfactory index of the degree of bleeding than the use of such terms as profuse, gross, massive or copious hemorrhage, which may be variously interpreted.

The patients in this series were further classified according to the method of treatment, as follows:

1. Two hundred and seventy-one patients were treated by an initial period of fasting of variable duration followed by a Sippy type of diet. Thirty of the

4. Sixty-four patients were treated by a combined method. On admission to the hospital food was withheld for one day, or longer if bleeding continued. During this time venoclyses of 5 per cent dextrose in physiologic solution of sodium chloride to which were added 300 mg. of ascorbic acid and 25 mg. of thiamine hydrochloride were slowly administered. When necessary, indirect transfusions of 250 to 500 cc. of citrated blood were slowly given. If whole blood was not available, serum or plasma was used. The daily fluid intake during this period was limited to about 3 per cent of the body weight. When bleeding had ceased, as evidenced by a stabilized blood pressure, pulse, blood findings and the clinical impression, hourly feedings of 1 ounce (30 cc.) or more of whole milk were given for one day or longer. If well tolerated, an ounce or more of cereal was given alternately with the milk every half hour for one or two days. During this time the fluid intake was supplemented by proctoclyses or venoclyses if necessary. Thirty-three patients in this combined group, who had no pain, had the feedings of milk and cereal followed, on the fourth to the seventh day after admission, by a diet consisting of cereals, cream soups, bread and butter, custards, jello, junket, milk, raw and soft boiled eggs, baked and mashed potatoes and puréed bland vegetables. These foods were given in increasing amounts for five days, when broiled white fish, minced chicken, lamb and scraped beef were added.

At this time no restriction was placed on the patient's appetite. Thirty-one patients in this combined group who were in pain had a duodenal tube inserted on the fourth to the seventh day after admission. When the tube reached the second portion of the duodenum, feedings consisting of one egg, 8 ounces (15 cc.) of milk and 1 tablespoon of lactose were given every two hours through the tube, as well as 500 cc. of a 5 per cent dextrose solution or of tap water, twice daily. The total daily intake was about 2,400 calories. The duodenal feedings were continued for two weeks, after which a liberal diet was given by mouth. The average period of bed rest was three weeks and the total hospital stay about four weeks. Of the 64 patients, 1 died of exsanguination. She was treated by a combination of initial restriction and duodenal alimentation. The mortality for this group was 1.6 per cent.

Morphine and the barbiturates were administered as indicated to insure mental and physical rest. Alkaline powders, similar to the original Sippy formulas, or colloidal aluminum hydroxide preparations, or the Meulengracht powder with ferrous lactate were employed. Iron preparations were prescribed as indicated, as were thiamine hydrochloride, ascorbic acid and menadione.

any indiscretions, physical exertion and overwork. Trauma to the abdomen was stated to have occurred in 1 case. The greatest number of bleeding episodes occurred from the latter part of October to the early part of March, which corresponds to the increased incidence of respiratory infections. Bleeding followed intoxication in a few cases but more frequently it occurred in those in which small amounts of alcohol were taken with meals. Emotional strain manifested itself mainly in worry over financial matters, business or profession, family illness and domestic difficulties.

ANALYSIS OF MORTALITY

Thirty-six patients in this series died. There were 29 men and 7 women. The youngest was 22 years old and the oldest 86, the average being 53 years. The duration of their symptoms varied from three to thirty years, the average being five and six-tenths years. In 3 cases the onset of the fatal hemorrhage was the first symptom. Of the 36 patients, 23 died during their first hemorrhage, 10 during their second, 2 during their third and 1 during his sixth hemorrhage. Thirteen had a gastric ulcer, 20 a duodenal ulcer, 2 both gastric and duodenal ulcers and 1 a hemorrhagic gastritis of a resection stump.

* Mortality from bleeding per se, excluding cases with complicating diseases

The experience with the four methods of treatment has been analyzed according to comparable grades of bleeding in table 2 and in the age groups above and below 50 years in table 3. In both tables, the influence of complicating diseases on the mortality is shown.

Twenty-eight of the 408 patients included in this series came to operation after a period of medical treatment varying from one day to three weeks. Twenty-three were originally treated with the restricted dietetic regimen. Four of these died postoperatively. One was treated by the Meulengracht diet and died following an operation for a perforation. Two patients were originally treated by duodenal intubation and 2 by the combined method. All 4 survived surgery. Five of the patients who came to operation had grade 1 bleeding, 9 grade 2, 4 grade 3 and 10 grade 4. In table 4 the mortality percentages of medical treatment alone and of both medical and surgical treatment above and below 50 years of age are shown.

There were 3 patients who were treated with Andersen's diet and 6 with a continuous intragastric drip of colloidal aluminum hydroxide. These were not included in this series because they were too few in number to permit any conclusions.

CONTRIBUTORY FACTORS

The factors which played a role in precipitating the hemorrhages in this series were, in the order of frequency, infections of the upper part of the respiratory tract, alcoholic beverages, emotional disturbances, diet-

Eighteen of the 36 patients who died, or 4.4 per cent of the total, had other diseases in addition to the bleeding ulcer which contributed to the fatal outcome. Of these 18 patients, 8 had grades 1 and 2 bleeding, of whom 7 were over 50 years of age. The remaining 10, of whom 6 were 50 years of age or over, had grades 3 and 4 bleeding. The complicating diseases were cerebral accidents, coronary thrombosis, congestive heart

TABLE 4.—Comparison of Mortality Above and Below 50 Years of Age on Medical and Both Medical and Surgical Treatment

Total	380	31	8.2	28	5	17.9

failure, renal disease, perforation of the ulcer, adenocarcinoma of the rectum and bronchopneumonia.

Of the 36 patients who died, 26 received transfusions, which were direct in all but 1 instance. Bleeding was not the sole cause of death of 11 of these 26 patients. The mortality rate in the entire series increased with the severity of the hemorrhage, whether transfusions were given or withheld. As the severity of the bleeding increased, a greater proportion of the patients received transfusions; 76.5 per cent of the 170 patients who

received transfusions, as compared to 28.6 per cent of the 238 patients who received no transfusions, had grades 3 and 4 bleeding. The patients in this series who received no transfusions were chiefly those who had a single hemorrhage without recurrence of bleeding during their hospital stay; a lower mortality is to be expected in these cases. On the other hand, 3 patients with grade 4 bleeding received five, seven and eight transfusions respectively and survived. It was difficult in many cases of recurrent bleeding to avoid the conclusion that transfusion was an important factor in the survival of the patient. On the other hand, with an exsanguinating hemorrhage or a complicating disease a fatal outcome could not be charged to transfusions.

In view of the statement which recurs frequently in the literature that transfusions increase the mortality by raising the blood pressure and dislodging the clot, it was thought of interest to compare the mortality rate of patients with and without hypertension. In this series there were 42 patients whose blood pressures on admission ranged from 150 mm. to 235 mm. of mercury. Based on Allen's²³ statement that a systolic blood pressure of 140 is a hypertensive level, 26 patients whose blood pressures ranged from 140 to 150 were included in this group, making a total of 68 patients, or 16.6 per cent of the series, who had hypertension. One may assume that the usual blood pressure of these patients was higher than that recorded during the hemorrhage. Of the 68 patients, 8, or 11.8 per cent, died, as compared to a mortality of 8.2 per cent in patients without hypertension. Of the 8 patients with hypertension who died, 4, or 5.9 per cent, died of exsanguination, as compared to 4.1 per cent of patients without hypertension, in whom bleeding was the sole cause of death.

COMMENT

Quite apart from the therapeutic procedure employed, the mortality in a series of cases of bleeding peptic ulcer is influenced by three factors: the severity of the bleeding, the age distribution and the presence of other organic diseases which determine or contribute to an unfavorable outcome. Differences in these factors probably account for the varied mortality statistics presented by many authors.

The need for grading the bleeding as an index of severity is emphasized by the demonstration that the ingestion of 50 to 80 cc. of blood is sufficient to produce a tarry stool.²⁴ The persistence of a tarry stool or of occult blood does not in itself indicate continued bleeding, because the former often persists for several days and the latter for one or two weeks after the hemorrhage has ceased. It is generally recognized that the mortality in bleeding peptic ulcer is higher in the older age group, as the result of arteriosclerosis and complicating diseases which may result in an unfavorable outcome even with a mild hemorrhage. Forty-eight and eight-tenths per cent of the patients in this series had grades 3 and 4 bleeding with a mortality of 14.1 per cent, as compared to a mortality of 3.8 per cent in those with grades 1 and 2 bleeding. Of the patients in this series 38.8 per cent were 50 years of age or over with a mortality of 16.6 per cent, as compared to a mortality of 4.8 per cent in those under 50 years of age. Fifty per cent of the fatalities were of patients who had complicating diseases. There are certain com-

plications which may make a fatal outcome inevitable but there are others, such as circulatory failure, azotemia and perforation, which may in part if not entirely be the result of the therapeutic procedure employed.

While mild uncomplicated cases do not, as a rule, present any problem, the treatment of severe gastroduodenal hemorrhage involves the following objectives: to aid in the arrest of bleeding, overcome shock and dehydration, combat anemia and depletion and prevent recurrence of hemorrhage. In the presence of continued bleeding, mental and physical rest are essential. The immediate need in these cases is not for food but usually for the restoration of the water balance to prevent or overcome shock, dehydration and extrarenal azotemia. If the daily parenteral fluid intake is kept to about 3 per cent of the body weight and administered slowly, there is little or no danger of increasing blood volume beyond its normal range. The regulation of the water balance is essential to the maintenance of normal function of the kidneys, which are burdened by an increased urea production at a time when the circulating blood volume is decreased. The resultant extrarenal azotemia is not proportional to the anemia,²⁵ and persistently high urea nitrogen levels indicate a bad prognosis, a fact which is corroborated by our experience in this study. Jones,²⁶ in analyzing a series of 39 fatalities, found that dehydration was an important factor in 18, and that 7 persons who had uremic blood levels did not die of anemia. Small citrated transfusions, frequently given, should be employed if the anemia is severe. The contention that transfusions raise the blood pressure, thereby dislodging the clot, cannot be directed to slowly administered drip transfusions, for Jones²⁷ has shown that transfusions of this type given in amounts up to 2,650 cc. daily produce no rise in blood pressure.

Our experience has been that progress was more satisfactory with food restriction until the active bleeding stopped. It was deemed advisable in all cases to withhold food for at least twenty-four hours after admission until it was determined that hemorrhage had ceased, at which time food was permitted in small amounts. Melena or occult blood in the stool was not regarded as a contraindication to food. If the small feedings were well tolerated, the diet was quickly increased. For patients without pain, a liberal diet was given by mouth. For those with pain, the increase in diet was accomplished by duodenal alimentation.

Meulengracht⁹ has stated that food in the stomach does not increase or protract the bleeding. In this connection it is of interest to note that he was inclined to think that the bleeding had stopped in most of his cases before arrival at the hospital, and that on the whole they were of a milder character than the hospital cases in England. Five of the ten fatalities in his series of 491 cases were due to bleeding which recurred from two to nineteen days after admission. In our series of 39 patients treated with a Meulengracht diet from the time of admission, 7 patients, 3 of whom died, had a recurrence of bleeding on the second to the eighth day. In addition, 3 patients experienced severe pain, and 1 of these died of a perforation. Meulengracht did not cite the age distribution of his patients.

The decision as to surgical intervention in bleeding peptic ulcer is a difficult one. The gastroenterologist hesitates to advise surgery because medical measures alone are frequently successful even when the situation appears critical. The decision cannot be made in advance based on statistical data alone but should be made in each case by weighing the severity of the bleeding, the ability of the patient to withstand radical surgery, the presence of complicating diseases and the skill of the surgeon. We have adopted the following procedure: If bleeding continues notwithstanding medical measures, the surgical division is consulted and the patient observed by both divisions. If after the use of transfusions the systolic blood pressure remains at 90 or below, the pulse rate 130 or above and the hemoglobin 35 per cent or below, surgery is advised in the absence of a complicating disease which would render operation futile.

Another problem which frequently arises is whether to advise an interval operation to prevent a recurrence of hemorrhage. In this series 64 per cent of the fatalities resulted from the first hemorrhage. One should be guided in making a decision as to an interval operation by the ability and willingness of the patient to avoid the contributory factors previously mentioned and the presence or absence of complicating diseases. It must be borne in mind that surgery does not always succeed in preventing a recurrence of hemorrhage. Thirty-nine of the patients in this series had had a gastroenterostomy prior to their bleeding episode. Three had hemorrhages in from one to three years following a subtotal resection, two of which were from anastomotic ulcers and one from a diffuse gastritis of the stump which resulted in fatal bleeding.

Gastrosocopy may be helpful in the interval between hemorrhages in determining the source of bleeding. In this series, gastrosocopy revealed that 2 patients had an erosive gastritis and that 2 others had marginal ulcers which were not detected by other means.

SUMMARY

A comparative study of various methods of treating bleeding peptic ulcer was made in a series of 408 patients. A basis for grading the severity of the bleeding was evolved and the influence of age and of complicating diseases on mortality determined. The data obtained in this study revealed the following:

1. Patients with mild uncomplicated hemorrhage progressed favorably with any of the medical methods.

2. Fifty per cent of the fatalities were of patients with complicating diseases; the latter accounted for all deaths of patients with grades 1 and 2 bleeding.

3. The total mortality rate below 50 years of age was 4.8 per cent, as compared to 16.6 per cent for patients 50 years of age or over.

4. Below 50 years of age the mortality rate for surgically treated patients was 16.6 per cent, as compared to 3.9 per cent on medical measures alone; while above 50 years of age the respective mortality percentages were 20 and 16.4.

5. The mortality rate with the restricted dietetic regimen was 11 per cent, of which 5.2 per cent were due to bleeding per se; with the Meulengracht diet, 10.3 per cent, of which 5.1 per cent were due to bleeding per se; with duodenal intubation, 2.9 per cent and with the combined method herein described, 1.6 per cent; in the latter 2 instances the fatalities were due to exsanguination.

ABSTRACT OF DISCUSSION

ON PAPERS OF DR. EUSTERMAN AND DRS.
RAFSKY AND WEINGARTEN

DR. NATHANIEL E. REICH, Brooklyn: Until such time as definite factors responsible for the formation of peptic ulcers are discovered, the treatment must be empirical and symptomatic. Treatment of hemorrhage presents four problems: 1. Stop the hemorrhage. 2. Keep the patient from dying from shock or circulatory failure. 3. Treat the ulcer. 4. Treat the anemia. In stopping the immediate hemorrhage, morphine is the drug of choice. It has been objected that morphine frequently excites nausea and vomiting. However, much of the recent experimental evidence indicates that this drug produces a fall in tone, a decrease in amplitude of rhythmic contraction and a decrease in the work performed by the stomach. I have found that therapeutic doses exhibit a definite inhibition of the fasting gastric secretion in the majority of instances. In the small percentage of patients that retch constantly, it may be advisable to wash the stomach rapidly with hot saline solution. Besides stimulating clot formation, this washing also gives direct information concerning the continuation or the recurrence of bleeding. Most physicians are in agreement that the danger of increasing hemorrhage by raising the blood pressure by transfusion is extremely slight if it is given by the slow, intravenous drip method. Jones has given as much as 1,200 cc. by this method, with no evidence of continued bleeding. I have found similar results. Besides replacing blood volume, proteins and hemoglobin, transfusion has the additional advantages of acting as a powerful hemostatic and hemopoietic agent. At least 80 per cent of the lost blood should be replaced by whole blood or blood plasma. Indications for blood transfusion are: 1. Systolic blood pressure of less than 75 mm. 2. Pulse rate of more than 140 per minute. 3. Hemoglobin of less than 35 per cent. 4. Shock, delirium, persistent headache and restlessness. An excellent consideration of medical treatments of the ulcer has already been mentioned by Dr. Rafsky. Anemia is best treated with oral iron preparations. The Meulengracht diet produces a more rapid regeneration of red blood cells and hemoglobin. Small transfusions may be found advisable about one week after the hemorrhage becomes quiescent.

DR. JOHN DAY GARVIN, Pittsburgh: I will confine my discussion of Dr. Eusterman's paper to presentation of 2 cases. A woman of 60 with a vague dyspeptic history of six weeks' duration presented in a roentgenogram a very small ulcerating lesion on the lesser curvature. I initiated an ambulant regimen. Within six weeks there was a great increase in the size of the lesion. The fact that I was dealing with a malignant ulceration was now apparent. At operation, resection was done with fair facility. The pathologic diagnosis locally, and ultimately by Broders, was that of a grade 4 carcinoma. After fourteen years the resected stomach seems perfectly normal and the patient insists that she is "just fine." In this case medical therapy was not only not misleading but, indeed, furnished the diagnostic base for the proper aggressive action. The second patient is a woman of 55 with a typical ulcer history of five years' duration. As the roentgen appearance was that of a large ulcerating lesion on the greater curvature, I insisted on prompt surgery. She would not submit to an operation and was placed on an ambulant ulcer regimen. She got complete relief from all discomfort, and the roentgenologic picture changed decidedly. The ulcer niche decreased persistently in size, ultimately almost disappearing. I did not see her for five months, at which time the picture was much as before, save for an increase in the constricting nature of the lesion. She consulted another doctor who was quite certain of the benign nature of the "ulcer" and utilized a four weeks intensive hospitalization regimen. After this he too suggested surgery. The surgeon, a competent one, told me that it was definitely a benign ulcer. The pathologic diagnosis was adenocarcinoma. My colleague was completely misled by the results of medical therapy. Subjectively they were, indeed, all that could be asked. As has been said by Dr. Eusterman, the niche of a supposed gastric ulcer may diminish in size or even disappear roentgenologically under non-operative treatment but may still turn out to be malignant, the improvement being caused by the subsiding of an inflammatory reaction associated with the malignant ulcer.

DR. JAMES F. WEIR, Rochester, Minn.: In any discussion on peptic ulcer it is necessary to distinguish gastric from duodenal ulcer. The diagnosis usually is accomplished by roentgenologic examination. Because the roentgenologic diagnosis of gastric ulcer depends primarily on the demonstration of a crater, the progress of healing can be followed readily. However, because the roentgenologic diagnosis of duodenal ulcer depends on a persistent deformity of the cap, craters are demonstrable in only 20 to 40 per cent of the cases, and because this deformity usually persists after healing there remains no satisfactory roentgenologic finding by which the activity, inactivity or healing state of duodenal ulcer can be determined. Gastric ulcers usually can be visualized through the gastroscope, but duodenal ulcers are beyond the reach of this instrument. In the medical treatment of gastric ulcer, certain principles are well established and many gastric ulcers can be shown to fulfil the requirements. Failure to do this is not necessarily a sign that the ulcers are malignant but may indicate chronic induration, a deep crater, walled off perforation or hourglass contraction, and on such evidence the ulcers may be classed as intractable and requiring surgical treatment. The problem of duodenal ulcer is somewhat different. Experience at the Mayo Clinic is similar to that of others; namely, that 75 to 80 per cent of these patients usually can be handled satisfactorily by medical measures, malignant changes practically never occur and in cases in which acute perforation, obstruction and repeated hemorrhages occur treatment is definitely surgical. In addition to these surgical cases there remains a group of cases in which severe symptoms, such as long duration of symptoms, progression in frequency and duration of attacks, lack of remissions, increasing severity of pain, nocturnal awakening, posterior extension of pain, lessening relief from food and failure to respond satisfactorily to medical treatment, appear. These symptoms usually mean induration, chronic penetration or beginning obstruction, for which surgical treatment should be instituted before the patient becomes debilitated or demoralized by pain or economic stress.

DR. SARA M. JORDAN, Boston: Dr. Eusterman's paper revives the most important problem in gastroenterology. No one who knows the statistics of incidence of cancer of the stomach can fail to be impressed by them. A recent review of our cases of gastric ulcer leads us to the following conclusions: To a confirmation of certain points in which we have believed for years; namely, that neither the size of the ulcer nor the age of the patient nor the presence of normal acid or hyperchlorhydria should lessen our suspicion of carcinoma, for some of our largest lesions have been benign and some of the smallest malignant, and malignant lesions occur often enough in the young, and benign ulcers often enough in the middle aged and old, and acid is present often enough where the lesion is malignant, so that these three criteria of size of ulcer, age of patient and presence or absence of acid have no actual practical value in the diagnosis of the individual patient, even though accumulated data on these points show a statistical trend. To a feeling of confirmation of the policy which we have practiced for many years, namely that the three criteria of complete disappearance of occult blood, x-ray defect and symptoms, are proof of healing. I would add recurrence as an indication for resection and shall not be unhappy if we have many benign lesions resected, for in the present fortunate era of almost perfected gastric resection the danger from the mortality of resection is less than the danger of gastric cancer as a sequela of recurrent gastric ulcer. Two other points are: (a) We believe that all greater curvature lesions are malignant. (b) Posterior wall ulcers, either of the median or of the prepyloric area, because often embedded in adjacent organs, cannot heal as readily as those which are not so embedded, nor can their healing be as well visualized fluoroscopically or gastroscopically. Hence, since many of the prepyloric lesions are on the posterior wall, their differentiation is more difficult and, if allowed to continue unhealed, a malignant condition may result. Even with perfected surgery it is (1) unnecessary to resect all gastric ulcers, (2) essential that to the former three criteria for benignity a fourth be added, namely a failure to recur, and (3) necessary to exercise the greatest care to make certain that complete healing has occurred and that, where there is doubt because of recurrent occult blood or of difficulty in following the lesion to complete healing because of the location of the ulcer or the management of the patient,

resection should be done. There should be a careful evaluation of the behavior of the stomach wall adjacent to the ulcer, in addition to the gastroscopic appearance of the mucosa and the closing of the ulcer.

DR. SIDNEY A. PORTIS, Chicago: Increasing clinical experience has not deterred me from my original position because I have not seen any evidence presented to make a definite differential diagnosis preoperatively in a questionable lesion. Even with the gastroscope no clear differentiation can be made. I cannot understand how a gastroscopist can be sure that a given lesion is benign when a surgeon with equally good clinical experience, the abdomen open, the lesion in his hand, cannot make a final diagnosis. Therefore, as I maintained years ago and still maintain, I would trust only the microscope in making this fine differential diagnosis. I still feel that gastric lesions, for the most part, are better handled by the surgeon. I am not discussing persons in their early twenties with a small, acute ulcer, but particularly that group of patients beyond 35 years of age who are good operative risks. I am convinced that the mortality and morbidity which would accrue in handling these early lesions surgically would be far less than a similar large series of cases handled medically. I think Dr. Eusterman will recall a case that I sent up to the clinic for review, in which the gastroscopist made a definite diagnosis of carcinoma with achylorhydria. Exploration was performed and a resection of the lesion failed to reveal any evidence of malignancy. With regard to Drs. Rafsky and Weingarten's statistics, I think we ought to be careful about the evaluation of the morbidity and mortality that accrue from surgical intervention in bleeding ulcers. I do not think we are quite fair in comparing our results with others because, for the most part, these patients have surgical intervention when procrastination and medical measures have long since failed. I feel that patients who come to our attention with exsanguinating hemorrhages are better handled at the outset by surgeons than to go through the trials and tribulations of medical management. When we are able to evaluate our statistics from both sides of this problem, namely those treated early from the standpoint of surgery and those from the standpoint of medical management, we shall be in a better position to say which would be the better type of treatment. It is interesting to note how frequently the findings at operation will impress on the mind of the medical man the futility of continued medical treatment in these complicated ulcer cases.

DR. J. SHELTON HORSLEY, Richmond, Va.: We have come a long way since thirty years ago when the late Dr. John B. Deaver in his dramatic manner said "the only cure for peptic ulcer was the aseptic scalpel." We now know that a young man who has had an aseptic scalpel applied to him for a peptic ulcer of the duodenum in the way of a gastroenterostomy and has high gastric acid is in a very unhappy situation. The great majority of peptic ulcers of the duodenum are better treated by medical means. And by "medical means" I imply that the treatment of the patient is more important than the treatment of the disease. It is a problem of proper living in a quiet environment, just as much as, if not more than, diet and drugs. In the treatment of hemorrhage we have also changed a good deal. Surgeons and medical men are not as antagonistic as they used to be. The statistics of Drs. Rafsky and Weingarten would doubtless show even more strikingly the difference in the mortality of certain groups if they had put his age limit down to 40, for instance. Over 40 or even 35 years of age the mortality of hemorrhage from a peptic ulcer increases alarmingly, and the need for surgical intervention is very much greater. No matter what the blood count is, within reasonable limits, if the blood pressure is too low for too long the patient may get in such a state of shock that even transfusions of plasma or of blood cannot save. Dr. Eusterman has given, as usual, a splendid paper. There have been many cases of what appeared to be benign ulcer that have proved to be malignant. They are more important than cases of what appeared to be malignant ulcers that were really benign. One of the most important things we can bring out here is the fact that Dr. Eusterman and others have emphasized: In practically every early case of gastric cancer, medical treatment for ulcer will relieve the clinical symptoms for a time. This fact has been thought to be a therapeutic test for showing a benign lesion, just as giving quinine is for malaria. This is a common cause of delayed diagnosis

and treatment. If operation for a peptic ulcer is indicated, a partial gastrectomy should, as a rule, be done. The indirect or halfway procedures, such as pyloroplasty and gastroenterostomy, are often unsatisfactory.

DR. EVERETT D. KIEFER, Boston: If we cannot treat the condition satisfactorily our only answer to the problem is possible prevention, and that means that it is important for both the physician and the patient to realize that ulcer is an intermittent disease and a progressive disease, and that with each attack there is added damage to tissue, increased scar formation, and if this is allowed to accumulate over a period of years we get the intractable peptic ulcer; therefore it is important for the patient to establish himself on a regimen for the control of this disease. We do not speak of cure; we speak of continued control, which means a constant, a permanent regimen that will keep him free of symptoms at all times, and it is best when it is controlled by the physician by occasional examinations to show that there is not accumulating additional anatomic change in the duodenum.

DR. HENRY A. RAFSKY, New York: We found that in the initial stage the immediate problem was the restoration of the water balance. If anemia was present citrated transfusions were employed, but in this connection it should be borne in mind that the criteria by which anemia is judged may be deceptive in the early stage. Lyon and Brenner made a comparative study of the regeneration of blood in patients treated with Meulengracht and Sippy plans respectively and found no difference in blood regeneration with either method. With reference to a systolic pressure of 75 mm. of mercury, we think that this is a dangerously low level to wait for. If the blood pressure fell below 90 in our cases, notwithstanding repeated transfusions, we felt that surgical intervention was indicated. Atropine was not used. With regard to surgery, it seemed that patients below 50 years of age had a better chance to survive with medical measures. Statistically speaking there was not much difference in the mortality rate in patients past 50 years of age whether medical or surgical measures were employed. It must also be borne in mind that bleeding episodes do occur after surgery. In this series the rise in the mortality rate was most striking after 50 years of age.

DR. ALBERT F. R. ANDRESEN, Brooklyn: Care must be taken not to assume that the symptoms which a patient has must be due to an ulcer seen six months or two years before. The symptoms are usually due to something entirely different. The lessons we have learned call attention to the importance of repeated and careful check-up in the presence of any ulcer, large or small, especially if it is in the stomach, and regardless of whether the symptoms have cleared up, because often the persistence of ulcer and of deformity may not be accompanied by intractability of symptoms. There has been pointed out the importance of careful interpretation of x-ray and other findings. I agree with Dr. Jordan with regard to the size of the crater in gastric ulcer as being no indication of whether carcinoma is present or not. We must recognize small carcinomas if we are going to cure people with them at all. Dr. Eusterman showed us carcinomas in young people. All lesions must be frequently checked by x-ray examination to make sure they are not malignant. Large craters may decrease in size as the result of subsidence of edema and inflammation, but irregularities usually remain. The x-ray examination may be a better criterion of carcinoma than the operation. Most cases of duodenal ulcer seen on the operating table are of the complicated type, with large masses of adhesions, induration and old perforation. That is found much more frequently than formerly. Formerly they were not recognized in advance but with more careful spot-film check-up they are seen almost as often as similar gastric ulcer complications and differentiation must be made between irritability and fixation, which can be done by fluoroscopy and the spot films, and persistence of crater as indicating a pocket can also be recognized. As Dr. Portis said, these cases should not be tampered with by medical treatment. They require operation. We should all realize that we should not say that there is a failure of medical treatment in these cases but recognize from the start the surgical indication and follow the patients for a time, with further check-up to make sure we were right that they were surgical from the start.

DR. GEORGE B. EUSTERMAN, Rochester, Minn.: Apropos of some features mentioned by the discussers, I noted in the paper that over one fourth of the carcinomatous gastric lesions of all types give rise to symptoms indistinguishable from chronic benign ulcer and unfortunately may also temporarily respond favorably to treatment. Since the publication of the section program in *THE JOURNAL*, several physicians have communicated with me and have related experiences similar to my own but have not reported them. It is not the purpose of this paper to serve as a green light to every surgeon to operate indiscriminately on every patient with a gastric ulcer, for we know that the operative mortality and morbidity by and large would be prohibitive. It is also to be remembered that the great majority of such small ulcerous lesions are benign, and many will respond favorably to adequate medical therapy. Case 3 is illustrative of the slow progress of some carcinomas. Symptoms may be present for four or five years. As the muscularis in this instance was intact, the pathologists inferred that the lesion was malignant from the outset. Such long duration of symptoms, taken into consideration with the occasional favorable response of ulcerating carcinomas to treatment, puts the proponents of the carcinomatous transformation of benign ulcer on the defensive. If cases such as I have reported herewith are not periodically checked following treatment, one could easily draw the false conclusion of regarding them as examples of carcinoma on ulcer, or carcinoma developing independently of the ulcer, when the patients returned later with extensive, often inoperable, carcinomatous involvement of the organ.

INTESTINAL AND MESENTERIC INJURY DUE TO NONPENETRATING ABDOMINAL TRAUMA

D. HENRY POER, M.D.

ATLANTA, GA.

AND

EDWARD WOLIVER, M.D.

CINCINNATI

Our purpose in this communication is to set forth the results of studies of a surgical problem for which treatment up to now has been significantly unsuccessful, as evidenced by a distressingly high mortality rate. These studies regard the little-understood injuries to the intestine and the mesentery by force which does not penetrate the abdominal parietes, and they were occasioned by recent clinical experiences in which the unfortunate outcome, while expected and reasonably explained, yet seemed preventable. During the past year we have observed 3 patients with rupture of the intestine, in 1 of whom the diagnosis was obvious and prompt operative treatment was followed by recovery. Operation on the other 2 patients was delayed until after the full development of generalized peritonitis, with resulting death. With full realization that recovery might have been possible had the diagnosis been made in the first few hours after injury and with a desire to determine the minimum information necessary to establish a tentative diagnosis leading to earlier surgical intervention, we have studied all available case records in the city hospitals of Atlanta and Cincinnati, and in addition we have studied the experiences of others to obtain such data as seem significant.

EXPERIENCE OF OTHERS

Many points of historical interest were uncovered in tracing the recorded information back to the first writings on this subject. The extreme fragility of the

intestine was known to Aristotle,¹ who said: "A slight blow will cause rupture of the intestine without injury to the skin." In the middle centuries autopsy reports of intestinal injury due to kicks by horses, blows and falls on the abdomen appeared, and it was noted that many times the injury seemed trivial or insignificant. The first successful operation for subparietal rupture of the intestine is said to have been reported by Sacherus² in 1720. Rambdohr³ in 1730 sutured a complete division of the intestine, with recovery of the patient, and the intact specimen was obtained later when the patient died with pleurisy. In the early part of the nineteenth century experiments were carried out on dogs by St. Croix,⁴ Travers⁵ and Gross⁶ in an attempt to find out the mode of production of intestinal injury and to discover a satisfactory method of suture. In the United States the first case report, by Annan,⁷ appeared in 1837, and in 1876 Gregory,⁸ in St. Louis, undertook to operate on a patient with such an injury, but the patient died.

At about this time many outstanding surgeons (Sims,⁹ Parkes,¹⁰ MacCormac,¹¹ Lonquet,¹² Curtis¹³ and

Appearance of intestine at operation. There is complete transverse division of the jejunum.

Makins¹⁴) made fervent pleas for surgical intervention in cases of abdominal trauma accompanied with suspected intestinal injury. Many operative attempts resulted, including the operation by Bouilly,¹⁵ whose

However, two years later (1889) a similar opportunity presented itself to Croft,¹⁷ and this time he was successful, with permanent recovery following suture of a perforation of the small intestine. Five months later (October 1889) Moty,¹⁸ in Paris, achieved the same result in a patient who was kicked by a horse in the umbilical area.

We have reviewed the experiences of other surgeons from 1889 to the present. Counsellor and McCormack,¹⁹ while adding a case report of jejunal rupture in a child of 8 years, had summarized and tabulated the available case reports up to 1935. They had found records of 1,313 cases, in 887 of which operation was performed and the gross mortality was 60.7 per cent. Diagnosis was established at autopsy in 426, raising the

ETIOLOGY

Mechanism of Rupture.—We believe there are three chief mechanisms by which nonpenetrating trauma of the abdomen may produce intestinal rupture. Most frequently such perforation results from a crushing injury in which the external force compresses the bowel against the spine or the pelvic bones. Occasionally tearing injuries may result from a violent force applied at a tangent to the body. Bursting injuries of the normal bowel are rare, except those which result from the introduction of compressed air into the anal canal.

In our series of 36 cases the accidents responsible for the injuries were divided as follows: (1) blows on the abdomen by blunt objects (14 cases); (2) falls (5 cases); (3) automobile wrecks (11 cases); (4) kicks in the abdomen (4 cases), and (5) other injuries (2 cases).

Predisposing Causes.—Aird²⁰ and Wilensky and Kaufman²¹ stressed the importance of hernia as a predisposing cause in their series of cases of traumatic rupture of the intestine, and we have found that hernia played an important part in 2 of our cases.

The analysis of our cases failed to show any influence of age on the incidence of intestinal rupture; however, there was a predominance of male patients and of white patients in our series (table 2).

SITES OF RUPTURE

The most frequent site of rupture in our series was the ileum (table 3). There were 4 patients with multiple perforations, 3 of whom died, and 6 patients with complete severance of the intestine, 5 of whom died

CLASSIFICATION OF CASES

We found it most convenient to classify our cases into three groups. We intentionally excluded cases in which either recovery or death occurred without operation or autopsy. The recoveries were probably few and the deaths many. The three groups of cases are as follows:

Group A.—In this group the diagnosis and treatment were delayed more than twelve hours after the accident. The delay may be attributed to failure of the patient to seek early medical attention because he thought the injury was trivial. On the other hand the delay may have been due directly to the physician's failure to appreciate the seriousness of the injury. In this group, with 17 cases, the mortality was 70 per cent.

Group B.—Diagnosis and treatment in the 14 cases in this group was promptly carried out. Accordingly, the mortality was only 35 per cent.

Group C.—In this group we placed cases of multiple severe injuries which occasionally overshadowed the serious abdominal condition. The mortality from injuries of this kind will always be high, even though treatment is instituted without delay. Our mortality in 5 cases was 100 per cent.

TABLE 4—Recovery and Death in Three Groups

	Recovery With Operation	Death With Operation	Death Without Operation
Group A Treatment delayed more than 12 hours	5	10	2
Group B Treatment prompt	9	5	0
Group C Multiple serious injuries .	0	2	3

SIGNS AND SYMPTOMS

Injury due to nonpenetrating abdominal trauma is accompanied by symptoms which vary to such an extent that no clear clinical picture can be set down (table 5). The reason is obvious when one remembers that in the first few hours after injury no sign or symptom may appear. In a large percentage of all cases studied the first symptoms to be noted were those of a complication of the injury, viz. peritonitis.

Further studies of intestinal injuries have produced several mechanical explanations for the delayed appearance of symptoms:

1. Incomplete rupture: In many instances severe bruising of the intestinal wall occurs which sloughs through several hours or even days later because of the development of local necrosis. Spillage is facilitated by the onset of peristalsis after the intake of food or fluids.

2. The production of intestinal paresis by the injury, which inhibits peristalsis for a sufficient time to allow an exudate of plastic lymph to seal the opening. After the patient has recovered from primary shock or after the intake of food, peristaltic action is resumed, with consequent leakage. Cope²² first described this interesting theory in 1914.

3. Prevention of leakage: Leakage may be prevented mechanically by the plugging of the opening by the mucosal layers or, in the case of complete transverse

division, by contraction of the circular musculature of the divided ends.

In a majority of cases shock was not noted when the injured person was first seen but developed as symptoms of peritonitis appeared. In several instances the evidence of shock came on rapidly after a silent period of approximately six hours, which corresponds to the time at which leakage of the intestinal contents into the

peritoneal cavity takes place. In other cases (group C) shock was severe when the patient was admitted, principally on account of other severe injuries.

The most constant symptom noted in a high percentage of all reported cases was abdominal pain or tenderness. It frequently is insignificant in the first hours but tends to increase steadily in severity. Tenderness may be localized to the site of the injury but may be elicited only by deep palpation. Cope²² has stressed the diagnostic value, in rectal examination, of tenderness due to the gravitation of irritating intestinal contents against the pelvic portion of the peritoneum. Vomiting, often associated with nausea, was noted to be the next most reliable symptom.

The pulse rate is the next important indicator. This may be normal when the patient is first seen but tends to rise steadily.

Distention, diminution or absence of hepatic dulness, the appearance of fluid in the flanks and roentgen evidence of air under the diaphragm all are considered positive evidence of peritonitis and are indications for immediate operation. Restlessness, rapid and superficial respiratory movements and definite pain on forced deep breathing are also positive evidence of complications such as hemorrhage or peritonitis.

In our series the only constant signs and symptoms were abdominal pain, tenderness and muscular rigidity. Nausea and vomiting occurred in less than half of the cases. Evidence of free fluid or gas within the peritoneal cavity was rare. The incidence of complete vasomotor collapse was infrequent. It is important, however, to reemphasize the early signs of vasomotor imbalance, such as pallor, diaphoresis, early tachycardia and abnormal blood pressure. These signs are a common feature immediately after accidents. The danger of waiting for signs of peritonitis, gross intestinal hemorrhage or severe shock cannot be overemphasized. External evidence of abdominal injury was present in only 16 of our 36 cases.

METHOD OF TREATMENT

The decision as to when to operate on patients with injuries of the type described requires keen clinical judgment. The importance of instituting treatment promptly is self evident when one compares the mortality in group A with that in group B. We believe it is sometimes wiser to risk an unnecessary abdominal operation (the mortality is low) while the patient's condition is still good than to delay operation, since in cases of perforation there is always a great increase in the mortality. However, since intraperitoneal and extraperitoneal hemorrhage without intestinal perforation may simulate rupture of a hollow viscus, the decision as to when to operate is exceedingly difficult in some cases.

The preoperative treatment for shock and dehydration is of paramount importance. When possible the choice of the anesthetic agent should rest with the specially trained anesthesiologist.

The operative procedure should be thorough but non-shocking. One must guard against overoperating. The choice of a method of intestinal repair varies according to the number and size of the lesions, the viability of the intestine and the general condition of the patient. Simple closure of the perforation, resection of the bowel and even exteriorization of the bowel in cases of severe injury are the most common procedures. Sometimes when resection is indicated and time is a factor the

Murphy button may be used to advantage. The question of cleansing the peritoneum is frequently raised. It is our opinion that the gross foreign bodies should be picked off carefully and the contaminated loops of bowel should be cleansed locally with physiologic solution of sodium chloride. This may be done by removing the affected loops from the abdomen and then rinsing them or occasionally by irrigating the loops intra-abdominally in the natural basins which may be formed by rolling or tilting the patient. Irrigation of the entire peritoneal cavity should be avoided. In cases of gross contamination in which treatment is instituted late the local implantation of sulfanilamide or a derivative within the peritoneal cavity and in the abdominal wound may prove a useful adjunct to therapy. This implantation is not advocated as a routine procedure until more convincing experimental work has been done. Closure of the abdominal wall should preferably be done by an expeditious but safe method, such as the use of through and through silver wire or silkworm gut sutures. Drainage of the general peritoneal cavity should not be attempted because of the attendant dangers and inadequacy.

Postoperative care should include adequate intestinal decompression. Proper electrolyte, protein and fluid balances are to be regulated by a careful recording of the fluid intake and output, hematocrit and plasma protein determinations and frequent determinations of the blood chloride levels. Sulfanilamide, sulfathiazole or sulfapyridine administered orally or parenterally is of distinct value in the postoperative care.

SUMMARY AND CONCLUSIONS

The problem of subparietal intestinal injury is concerned with early diagnosis, which in turn calls for prompt treatment before the development of peritonitis. Even under the most favorable circumstances (as in group B) the mortality is 35 per cent, which must be considered high in comparison with that for other surgical procedures, but this figure is doubled (becoming 70 per cent) when operation is performed after the onset of complications (as in group A).

Study of the cause of injury in 1,476 cases revealed the interesting fact that a high percentage of injuries were produced by a relatively small variety of accidents. These included injuries received in personal encounters in which the patient was struck or kicked or fell on the abdomen. Distention of the intestine with food or fluid contributed to the likelihood of rupture, as was evidenced by the fact that many injuries were received soon after the patient had eaten. In industrial accidents, another type, the damage was produced by a blunt object, such as an iron bar or a piece of timber, striking the abdomen with considerable force. The third type of accident by which intestinal injuries were produced was concerned with transportation, the accidents involving the automobile, motorcycle, train, street car, airplane and bicycle, frequently moving at a fast rate of speed. In accidents of this type many forces were applied simultaneously, in that the patient was in motion in one direction and came forcibly against a fixed object or an object moving in the opposite direction, so that a severe crushing injury was produced.

Since it is unquestionably true that intestinal rupture may take place beneath an intact and unbruised abdominal wall and that in some cases no symptoms can be detected during the early hours after injury, if the present high mortality is to be lowered, earlier

surgical intervention is required, and the decision to operate must be based in many instances on intelligent suspicion alone. This suspicion should necessarily be built on a careful study of the accident, with particular emphasis on the exact details of how the abdomen was struck. If the type of accident elicits suspicion, the patient should be observed for four to six hours, and if abdominal pain or tenderness on pressure can be evoked the indications for operation are adequate. A constant rise in the pulse rate makes such a procedure imperative. Decision not to operate is many times more dangerous than the hazards of an unnecessary exploration.

384 Peachtree Street, North East.

ABSTRACT OF DISCUSSION

DR. W. L. ESTES JR., Bethlehem, Pa.: In reviewing 2,217 consecutive cases of injuries of all types in our clinic we found that 32 represented abdominal trauma, an incidence of 1.4 per cent. Cody has reported deaths from trauma in Iowa in a three year period as being 5,744 with 53 abdominal traumatic cases, an incidence of 0.9 per cent. Clinically, abdominal trauma may be divided into (1) severe multiple injuries which are rapidly fatal but for which no treatment is of avail, (2) cases that obviously require immediate operation and (3) cases in which the diagnosis is doubtful and the indications for or against operation are not clear. In the proper care of this third group lies the greatest opportunity for saving lives and lowering the extraordinarily high mortality rate. All cases of abdominal trauma, no matter how trivial, in which a decision for operation cannot be immediately made should be kept under the closest observation. There are many cases of abdominal injury on record in which the symptoms of onset were apparently trivial but later, within four or five hours, definite evidence of a severe abdominal lesion, requiring operation, developed. With delay in operation, frequent reexamination should be made at least every thirty minutes—until definite conclusion for or against operation can be reached. Repeat blood counts should be taken every thirty minutes, and no opiate should be given. The upper jejunum and the terminal ileum are the most common locations for subcutaneous rupture or laceration of the intestine, because in these locations the mesentery is short and compression against the vertebral column can occur. Persistent or recurring pain and persistent vomiting with increasing pulse rate are most important. Boardlike, general or localized rigidity and symptoms of a spreading peritonitis will be present in the outspoken case. In the doubtful case an abdominal roentgenogram to demonstrate subdiaphragmatic free air may be helpful but, if negative, does not eliminate the possibility of intestinal rupture. Successful treatment depends entirely on the magnitude of the injury, early diagnosis of rupture, prompt decision that an operation is necessary and the correct time for and method of operative intervention. Decision for or against operation should be made within four or six hours of the accident. It is only by prompt recognition and early operation that the surprisingly high mortality in this deceptive lesion can be effectively reduced.

Unnecessary Investigations.—I admit that there are many occasions, many diseases, many patients who demand any or all of those investigations. What I object to, and what many patients object to, is that they are demanded every time, and they cost money. Indeed, this constant demand for widespread and often unnecessary investigations provides a large part of the reason for the familiar plaint that modern medicine is so expensive. Of course it is expensive if the patient has to run the gamut of all the specialties before he can be told he has a cold in the nose. Judicious selection of the investigations necessary to arrive at a diagnosis is as much a part of the physician's duty as a judicious selection of drugs in treatment.—Atkinson, Miles: *Behind the Mask of Medicine*, New York, Charles Scribner's Sons, 1941.

THE SIGNIFICANCE OF NECROTIZING PYELONEPHRITIS IN DIABETES MELLITUS

J. HARTWELL HARRISON, M.D.
AND
ORVILLE T. BAILEY, M.D.
BOSTON

While the physician treating patients with diabetes mellitus devotes much attention to the early discovery of infections, the importance of the infections involving the urinary tract has been underestimated. It is our purpose in this paper to discuss a severe form of urinary tract infection in patients with diabetes and the stages by which the final changes come about. The end result is a necrotizing pyelonephritis with extensive destruction of renal tissue. This complication of diabetes, unless recognized in its incipience, leads to a fatal termination. Most of the features of this form of pyelonephritis are seen occasionally in patients not suffering from diabetes. However, the severity, rapid progression and extent of necrosis of renal tissue are hardly to be found in the absence of diabetes.

In some recent surveys of the complications of diabetes, the infections of the urinary tract have not appeared especially common.¹ However, in others,² urinary infection has been regarded as a frequent and serious complication of diabetes. The urologist usually sees patients with diabetes after infection is already advanced and often only when irreversible impairment of renal function has occurred. It appears desirable, therefore, to emphasize the incidence of urinary tract infections in patients with diabetes and especially to investigate the early stages of such infections.

Ophüls'³ studies indicate that 4 per cent of persons coming to necropsy have an infection of the upper urinary tract which may or may not have been the cause of death. It has been demonstrated that about 20 per cent of people dying of diabetes mellitus have infection of the kidneys.² Thus, renal infection is found at necropsy five times as frequently in patients with diabetes as in the population at large.² However, a much smaller percentage of patients with diabetes are found to have urinary infection during life.⁴ It is reported that 6 per cent of 4,500 patients with diabetes mellitus had urinary infection and only 4 per cent needed urologic investigation.⁵ The discrepancy between 20 per cent at necropsy² and 6 per cent in life⁶ is too great to be accounted for by terminal infection alone. The lack of symptoms in the earlier stages and the consequent difficulty in recognizing the infection probably accounts in part for the discrepancy. It seems that a further search for bacteria in the urine of patients without symptoms of urinary tract disease would lead to finding the earlier stages more frequently and hence to earlier therapy.

In order to determine the incidence of asymptomatic bacteriuria in ambulatory patients, a group of 50 unselected diabetic patients was compared with another group of patients of similar age distribution in whom diabetes was not present. Although the group investigated is small, the results of the study are so definite that the inclusion of these data seems warranted. While the numbers were small, care was taken to have different age groups equally represented in the two series. Furthermore, the findings have been recorded as negative unless the bacteria or white blood cells were abundant. All female patients were catheterized; the specimens from male patients were voided after careful cleansing of the glans. The presence of bacteria was determined in unstained smears of the urinary sediment after centrifuging. The results were confirmed and the gross classification of the organisms established in smears stained by the method of Gram. The results are given in table 1. It will be noted that bacteria were present in the urine of 27 of the diabetic patients while

in the nondiabetic group bacteria were demonstrable in only 4.

Though the significance of bacteria as the only abnormality in the urine may well be questioned, the added presence of pyuria means that invasion of tissues by pathogenic organisms has taken place. The fact that pyuria was found in 10 of the diabetic patients but in only 2 of the nondiabetic group thus becomes of special significance.

Numerous bacteria were present in the urine six or seven times as frequently when diabetes was present as when it was absent. Pyuria was found five times as often among the patients with diabetes as among the controls.

Cultures were made from the urines of patients with diabetes but not from those of the control group. The results are given in table 2. The presence of bacteria in the urine was detected more often by culture than by examining the urinary sediment directly. This discrepancy is accounted for by the fact that the cultures are positive when organisms are present, regardless of their numbers; we judged the sediment negative when studied directly unless bacteria were found in abundance. The

organisms found by culture include most of the common invaders of the urinary tract. The incidence of staphylococci is greater than would have been expected from studies in the literature.⁶

In the well controlled diabetic patient, these urinary infections are usually asymptomatic. Their significance lies in the part they play when the patient's resistance is lowered by adverse circumstances. The peculiar fulminating form of necrotizing pyelonephritis to be described may well arise from these mild asymptomatic and often neglected instances of urinary infection in patients with diabetes.

The severe renal infections become manifest clinically by the appearance of fever, pain, hematuria and pyuria. Necrosis of the renal papillae is demonstrable on further investigation. Günther,⁷ in describing necrosis of the renal papillae in 10 patients, pointed out that diabetes was present in 7 of them. This stage has been demonstrated by pyelography.⁸ Necrosis of the pyramids is by no means confined to pyelonephritis complicating diabetes. As Mallory, Crane and Edwards⁹ have pointed out, involvement of the renal pyramids is one of the early lesions of experimental pyelonephritis. Furthermore, the papilla is the most frequent site for the origin of "primary" renal calculi.¹⁰ The irregular filling defect produced in the pyelogram by necrosis of the renal papilla in pyelonephritis bears a striking resemblance to that produced in renal tuberculosis, as shown in the accompanying illustration.

We present in detail the clinical and pathologic findings in 3 patients with progressively more severe necrotizing pyelonephritis complicating diabetes. Case 1 showed changes in the pyelogram early in the disease very much like those found in renal tuberculosis but due to necrosis of the renal papilla as the result of infection with pyogenic organisms. Case 2 presented a more extensive necrotizing infection which terminated fatally. In case 3, study of the kidneys revealed almost complete necrosis of renal tissue. The 3 cases indicate some of the stages through which low grade renal infection manifested only by bacteriuria passes to almost complete necrosis of the kidney.

CASE 1.—Miss V. M., aged 24 years, entered the hospital because of weakness and vomiting for several days. She had received treatment for severe diabetes mellitus over a period of eleven years. One year before admission she was treated for diabetic neuritis and six months before began to experience macroscopic hematuria. A month before, urinary infection due to *Escherichia coli* was discovered and treated unsuccessfully with mandelic acid and sulfanilamide.

The patient was found emaciated, with a temperature of 103 F. and a dry, red tongue. The blood pressure measured 120 mm. of mercury systolic and 60 mm. diastolic. Nothing abnormal was found on examination of the chest. There was diffuse abdominal tenderness but none in the flanks, and neither kidney was palpable. There was hyperesthesia over the left thigh and on the soles of both feet. Ankle jerks were absent, and the patellar reflexes were hypoactive. The Wassermann and Hinton tests were negative. Urinalysis showed a specific gravity of 1.022, a slight trace of albumin, sugar 4 plus,

tone 1 plus. There were many leukocytes and occasional erythrocytes in each high power field. The hemoglobin of the blood measured 82 per cent (Sahli), the erythrocyte count was 4,260,000 per cubic millimeter, the leukocyte count was 12,800 per cubic millimeter and the smear showed 90 per cent polymorphonuclear leukocytes and 10 per cent lymphocytes. Culture of the urine from the bladder yielded a growth of *E. coli*. The blood urea nitrogen was 14 mg. per hundred cubic centimeters.

Cystoscopy showed a chronic vesical inflammation without ulceration. The trigon had a granular edematous appearance and the bladder was atonic. The urine from the left kidney contained large numbers of leukocytes on several examinations, while that from the right kidney contained none at any time. Phenolsulfonphthalein excretion appeared in five minutes from the right kidney and in nine minutes from the left kidney. The total excretion in ten minutes from the right was 11 per cent and from the left 1 per cent. Cultures from the left kidney yielded a profuse growth of *E. coli* and from the right were negative.

The diabetes was controlled by diet and insulin. However, the patient continued to have a fever in the evening which varied from 100 to 103 F. There was no demonstrable response to

A left retrograde pyelogram in case 1, showing irregularity of a middle calyx and to a less extent of a superior calyx. This is the result of necrosis in the renal papillae. The changes shown in the pyelogram bear considerable resemblance to those produced by early renal tuberculosis.

either sulfanilamide or sulfathiazole. Pyelograms showed distortion of the left renal pelvis, as shown in the illustration.

Left nephrectomy was performed under ether anesthesia. On the third postoperative day the temperature rose to 104 F. and the leukocyte count of the blood to 22,000 per cubic millimeter. The blood urea nitrogen rose to 61 mg. per hundred cubic centimeters and the blood sugar to 770 mg. per hundred cubic centimeters on the fourteenth postoperative day. One week later the right kidney was tremendously enlarged and easily palpable yet nontender. The signs were those of a diffuse pyelonephritis with no evidence of either nephric or perinephric abscess. Improvement was slow but, as infection cleared, the diabetic state became controlled and renal function improved. The patient was discharged from the hospital three months after operation still showing evidence of a chronic urinary infection but the nonprotein nitrogen of the blood had returned to normal. Six months later the patient was well; she had gained 55 pounds (25 Kg.). However, since urinary infection persisted, the prognosis remained guarded.

The kidney removed at operation measured 12 by 6 by 5 cm. From the reddish brown external surface there projected many yellowish white knobbly elevations which varied from 2 to 5 mm. in diameter and which were raised 1 or 2 mm. above

the surrounding parenchyma. The markings of the cut surface were irregular. Small white areas were present in the cortex and outer part of the medulla; these were continuous with the elevations on the exterior. The surface of the pelvis was dull grayish white. No areas of ulceration were encountered.

Examination by microscope showed streaklike areas of inflammation extending through the kidney from pelvis to cortex. In these areas the glomeruli were fibrosed and the tubules somewhat dilated. The interstitial connective tissue was increased in amount and was infiltrated with many lymphocytes and a smaller number of polymorphonuclear leukocytes. A few gram-negative bacilli were found in the sections. The knobbly elevations were composed of areas of scar tissue in which all traces of renal parenchyma had been destroyed. The arterioles about these areas of scarring displayed moderate arteriosclerosis but no organized thrombi were seen. There was an extensive lymphocytic infiltration of the subpelvic tissues as well as an increase in connective tissue in this region.

The urinary infection was well advanced for months before its recognition and treatment. When the patient came to the hospital, chemotherapy was without effect. The lack of response is partly explained by failure of the drug to penetrate tissues whose circulation has been greatly diminished by chronic infection and partly by the fact that the diabetic state could not be satisfactorily controlled in the face of persistent infection. Atony of the bladder with accompanying residual urine played an important role in prolonging infection, particularly after operation. There were other evidences of neurogenic disturbances in addition to the vesical disorder, such as hyperesthesia of the legs and feet and loss of tendon reflexes. The hazard of nephrectomy for unilateral pyelonephritis is demonstrated by the extensive infection of the remaining kidney after operation.

Examination of the kidney after removal showed nodular areas of scarring, representing the end result of necrosis of renal tissue. There was evidence of active infection in other parts of the kidney. The process, then, is regarded as one which is progressing in some places and healing or healed in others.

CASE 2.—Mrs. E. B., aged 46, came to the hospital because of intermittent attacks of hematuria, frequency of urination, chills, fever, abdominal pain, nausea and vomiting. Mild urinary symptoms had been present for eight months, and the other symptoms had appeared during the previous two weeks. Seventeen years earlier she had had an attack of acute pyelonephritis during a pregnancy which ended in miscarriage. Eleven pregnancies resulted in nine healthy children, one stillbirth and the miscarriage just mentioned.

Lower abdominal tenderness was the only relevant finding on physical examination. The urine contained large numbers of leukocytes and erythrocytes; there was a slight trace of albumin and 2 plus sugar. Renal excretion of phenolsulfonphthalein was measured at 65 per cent the first hour and 25 per cent the second hour. The nonprotein nitrogen of the blood was 31 mg. per hundred cubic centimeters. The only abnormality demonstrated in intravenous urograms was dilatation and irregularity of the right renal pelvis. At cystoscopic examination the bladder was found to be diffusely inflamed; no other cause for hematuria was discovered. Cultures of the urine yielded a growth of *Staphylococcus albus* and non-hemolytic streptococcus.

After the patient had been treated for twelve days, improvement of the infection occurred and it was possible to control the diabetes by diet alone. The patient was discharged to the outpatient department, where treatment was continued but pyuria persisted.

Five months later dilation and curettage of the uterus was performed for postmenopausal bleeding. This was followed by a febrile reaction and an acute exacerbation of urinary infection. At cystoscopic examination under evinal anesthesia the

mucous membrane of the spastic bladder was covered with a shaggy gray exudate. Ureteral catheters could be passed only 3 cm. on each side. During the next three days the nonprotein nitrogen of the blood rose to 70 mg. per hundred cubic centimeters and the blood sugar to 350 mg. per hundred cubic centimeters, but sugar and acetone did not appear in the urine. The temperature varied between 102 and 103 F. The output of urine gradually diminished in spite of an intake of 3,000 to 5,000 cc. of fluid a day. Though the urinary output was reduced to 200 cc. a day the specific gravity of the urine did not exceed 1.010. The left kidney was palpable and tender. Incision and drainage of the left perinephric abscess and left nephrotomy were performed under local anesthesia. Death occurred soon after operation.

The anatomic diagnoses were acute and chronic pyelonephritis with necrosis and abscess formation, bilateral; multiple perinephric abscesses, bilateral; nephrostomy, recent; acute and chronic cystitis and ureteritis; peritonitis, generalized; glycogen in liver cell nuclei and in kidney.

The right kidney weighed 240 Gm., the left 360 Gm. Both kidneys were surrounded by fat tissue containing numerous small and large abscesses. After this tissue was removed there were uncovered numerous abscesses, some as large as 1.5 cm. in diameter. Beneath the intrinsic capsule was an accumulation of purulent material resulting from rupture of abscesses near the surface of the parenchyma. The kidney markings were almost completely obliterated, and but little uninvolved parenchyma could be made out. The grayish yellow renal tissue was very soft in consistency. The two kidneys were about equally involved in the process, although localized abscess formation was more conspicuous in the left kidney than in the right.

Microscopically the abscesses in the peripelvic fat were found to be composed of necrotic tissue, polymorphonuclear leukocytes and bacteria in large clumps. The general architecture of the renal parenchyma was very much obscured by numerous abscesses like those in the perinephric tissues. The amount of necrosis of renal tissue was large and the abscesses were almost bordering one on the other. Huge clumps of bacteria were found at the center of the abscesses. In the portions of renal tissue not involved in the necrosis there was intense engorgement of blood vessels. Glycogen deposits were found in the cytoplasm and nuclei of the convoluted tubules. The interstitial tissue was increased in amount and was infiltrated freely with lymphocytes and polymorphonuclear leukocytes. The subpelvic tissues showed a similar inflammatory cellular infiltration. The arteries and arterioles showed minimal sclerotic changes. While a few contained small thrombi, the degree of thrombosis did not appear out of proportion to the extent of the inflammatory reaction.

This patient, when first seen, had mild diabetes mellitus and a urinary infection which had been present for several years. In retrospect it is apparent that the latter condition was never adequately controlled. If treatment with sulfonamide compounds had been available at that time, the progress of the infection might have been arrested. However, as shown by case 1, the administration of these drugs must be started early in the course of the disease. While this is important in all instances of pyelonephritis, it assumes even greater significance when the pyelonephritis is complicated by diabetes. The fatal exacerbation of infection in this case followed dilation and curettage of the uterus under ether anesthesia. At necropsy the necrosis of tissue and abscess formation was very extensive. Even if the patient could have survived the infection, the loss of parenchyma would have been too great for renal function to continue satisfactorily.

CASE 3.—Mrs. E. F., aged 46, was admitted to the hospital because of fever, prostration, pain in the flanks and vomiting. The onset of symptoms began with a chill five days previously.

Prior to that time she had appeared well and there were no urinary complaints. Eleven years before, during pregnancy, she was told that she had diabetes and hypertension. No regular treatment of either condition was carried out after delivery.

On arrival, the patient was stuporous. The temperature was 104 F., the respiratory rate 35 per minute and the pulse rate 110 per minute. The mucous membranes were dry and the tongue was coated. Scattered rales were heard at the bases of both lungs. The heart was not enlarged. The abdomen was distended and there was a large rounded, nontender mass in the right flank which extended from beneath the costal margin almost to the iliac crest. A similar but smaller mass could be felt in the left flank. There were scattered areas of hyperesthesia over both lower extremities. The patellar and achilles reflexes were absent on both sides.

A plain roentgenogram of the abdomen showed the stomach and several loops of small intestine to be distended with gas. Cystoscopic examination was performed the next day. The bladder contained 200 cc. of foul smelling, bloody urine, and thorough irrigation was necessary to clear the medium. The entire interior of the bladder was covered with adherent clotted blood and gray exudate in the irregular areas.

The Wassermann reaction of the blood was negative. The nonprotein nitrogen of the blood measured 95 mg. per hundred cubic centimeters and the total protein 5.8 Gm. per hundred cubic centimeters with albumin 3.1 Gm. per hundred cubic centimeters and globulin 2.7 Gm. per hundred cubic centimeters. The urine contained a trace of albumin, sugar 1 plus and no acetone, but large numbers of leukocytes and erythrocytes. Studies of the blood showed a hemoglobin content of 75 per cent, erythrocyte count 3,600,000 and leukocyte count 7,900.

A diagnosis of bilateral renal infection was made. Right nephrostomy was thought indicated. Under local anesthesia the right renal fossa was exposed and found occupied by a dense mass of infected, necrotic tissue containing many bubbles of gas. The kidney was a tense, discolored, crepitant sac of necrotic tissue which, when opened, allowed the expulsion of foul smelling gas, clotted blood and urine. Drainage was instituted. The patient died four hours after the operation.

The anatomic diagnoses were acute pyelonephritis with multiple abscesses, extensive, bilateral; infarction and gangrene of kidneys, extensive, bilateral; necrosis of adrenals, extensive, bilateral; cystitis emphysematosa; peritonitis, generalized; pneumoperitoneum; acute splenitis.

The fat in each renal fossa was necrotic and reddish black, with a few yellow areas. Adjacent to both kidneys there were large masses of clotted blood. Both adrenals were reduced to a mass of friable, necrotic material; no viable adrenal tissue could be found. The kidneys were markedly increased in size, the right more so than the left. The renal parenchyma was extremely soft, friable and necrotic. It was infiltrated with numerous bubbles of gas, as were the surrounding tissues. Such structures as the cortex and the medulla could not be identified in the reddish black mass of renal tissue. There were no thrombi visible grossly in the larger branches of the renal arteries and veins.

E. coli was obtained in culture from material in the renal fossa taken at operation, and the same organism from the blood of the heart at autopsy.

There was but little renal tissue which even approached normal in morphology. Abscesses, mostly small, were scattered through the parenchyma in large numbers. The abscesses contained huge masses of bacilli morphologically consistent with *E. coli*. The tissue among the abscesses showed most extensive anemic infarction. Only after search could one find small groups of relatively normal glomeruli and tubules. Even in these regions there was heavy polymorphonuclear leukocytic infiltration. Slight intimal thickening was found in the medium sized and larger arteries. Many vessels near the abscesses contained partially organized thrombi. As these thrombi were traced into larger vessels they showed progressively less and less evidence of organization. In the largest vessels there was a thin layer of unorganized fibrin over the surface of the intima.

This patient's course is fully accounted for by the fulminating pyelonephritis due to *E. coli*. The urinary infection had probably been present long before the onset of the terminal illness. However, the patient had no symptoms referable to such an infection until five days before she was admitted to the hospital. The rapid progression of the infection was favored by the presence of diabetes mellitus, which had not been treated for years. The possible significance and gravity of urinary infection as a complication of diabetes is emphasized by the course of events in this case.

At necropsy the kidneys showed a most unusual degree of pyelonephritis with multiple abscesses and, in addition, very extensive infarction and gangrene. It is apparent that the regions of infarction resulted from thrombi which had their origin in small vessels about some of the abscesses. From these sites the thrombi were propagated centripetally, thereby leading to infarction of progressively larger areas of renal tissue. The lesion represents a fulminating pyelonephritis of an extent and degree not found elsewhere in our material and in few cases recorded in the literature. The complete necrosis of both adrenal glands resulting from extension of the renal infection probably was an important factor in the rapid course and fatal termination of the disease.

One would have expected, perhaps, that a renal infection with so many unusual features would have been caused by an uncommon organism. Our cultures, however, yielded only *E. coli* in spite of the fact that they were prepared aerobically, anaerobically and under partial carbon dioxide tension. A few gram-positive bacilli were also seen in direct smears, but they did not grow out in culture. The large masses of bacteria seen in sections of the kidneys were all gram-negative bacilli and hence were entirely compatible with the cultural findings. *E. coli* has been found in similar cases recorded in the literature.¹¹ There are two factors to be considered: one, the nature of the organism, the other, the resistance of the tissues invaded. The findings indicate that it was the second which was responsible for the end result in this case.

THE DEVELOPMENT OF NECROTIZING PYELONEPHRITIS

The ease with which infections are set up in the diabetic state would suggest that bacteria in the urinary tract are at least a potential hazard and one to be much more seriously regarded in the presence than in the absence of diabetes. When pyuria is present (as it was in one fifth of our series of unselected patients with diabetes) it may be assumed that a locus of infection has already been set up in the urinary tract and destruction of tissue has begun. These are the initial steps leading to the disastrous renal infections which have been discussed in the three cases just presented.

Once the infection has gained a foothold, its spread is greatly favored by the presence of diabetes. Thus infections which would be walled off in an otherwise healthy individual tend to spread so as to involve progressively greater amounts of tissue. One of the characteristics of the inflammatory reaction to certain organisms, especially the staphylococcus, is the formation of thrombi about the lesion. These thrombi tend to prevent extension of the infection by closing endothelial lined channels. Such thrombi occur in infections,

whether or not diabetes is present. In cases 1 and 2 the thrombi seemed to be in proportions commensurate with those expected to accompany that particular degree of infection. However, in case 3 the thrombi were propagated centripetally. The oldest and most completely organized ones were in small vessels about the areas of infection. The fresher and less organized thrombi were in larger vessels. The propagation of the thrombi, then, must be regarded as an important factor in the extreme degree of necrosis seen in the kidneys in case 3. Abscesses are frequent in many types of renal infections, but such extensive necrosis as that found here is comparatively rare. For this reason the diabetic state seems important in contributing to the end result.

THE RECOGNITION OF URINARY TRACT INFECTIONS IN PATIENTS WITH DIABETES

Certain simple measures may be adopted which will help to make an earlier diagnosis of urinary infection in patients with diabetes. Questions should be directed toward uncovering an alteration of urinary habits and instructions given as to the importance of any change encountered. Unfortunately, the patient who has had polyuria for years as a result of uncomplicated diabetes does not see a warning signal in increased frequency of micturition and may only diminish his fluid intake instead of consulting his physician immediately. The delayed appearance of prominent symptoms demands careful interrogation as to mild dysuria, nocturia, vesical discomfort and pain in the flank. In addition, any systemic manifestation which indicates that the diabetic state has become worse suggests a search for infection, and it is to be remembered that involvement of the urinary tract is not uncommon. Examination of the genitalia leads to the early discovery of phimosis, adherent prepuce (4 of 27 men examined), balanitis, pruritus vulvae and cervicitis. All these conditions may be the antecedents of serious infection in the patient with diabetes. Enlargement of the kidney or perinephrium may be discovered by abdominal palpation before any local symptoms have appeared. In addition to ordinary urinalysis, examination of the stained urinary sediment is of particular value in the early recognition of bacteria in the urine. When present, these should be verified by cultures. If bacteria are found on repeated examination, they should be considered as indicating an active stage of infection even in the absence of pyuria in the patients with diabetes. Glycosuria should of course be controlled and if bacteria continue to be present prompt investigation and treatment should be instituted. It is recommended that in addition to a search for foci of infection, a plain roentgenogram of the abdomen be obtained. Intravenous urography and cystoscopic examination are suggested if they seem appropriate for the study of the individual patient.

Pneumaturia¹² is more common in urinary tract infections in patients with diabetes than it is when this complication is absent. The condition is usually manifested by interrupted urination, which makes the patient aware of the passage of gas. *E. coli*, *Bacillus lactis aerogenes*, yeasts and *Clostridium perfringens* are the organisms that have been found. Analysis of the gas has indicated the presence of carbon dioxide, hydrogen, nitrogen and methane. As a result of fermentation of the urine, butyric acid, lactic acid and alcohol have been

12. Riley, Francis, and Bragdon, Floyd: Pneumaturia in Diabetes Mellitus: Report of Cases, J. A. M. A. 108: 1596-1599 (May 8) 1937.

recovered. The gas may be formed not only in the urine but also in the tissues of the kidney and bladder in severe forms of infection. Large amounts of gas in the renal tissues were seen at operation in case 3. Olsson⁷ has also demonstrated the presence of gas in the renal pelvis by roentgenograms. There have been several reports¹³ of cystitis emphysematosa in which the vesical wall is the site of multiple blebs filled with gas. This condition was present in case 3.

If beneficial therapy is to be instituted, it is necessary that infection be discovered early. Chemotherapy is well tolerated if the diabetic state can be controlled. Regulation of the diabetes, however, is difficult once infection has gained the upper hand. When a chronic inflammatory process has been established, impairment of circulation (by fibrosis, suppuration and thrombosis) prohibits an effective permeation of the tissues by a chemotherapeutic agent. Early drainage of infection, a proper diet, forced fluids and increased administration of insulin are general measures which apply in the treatment of any type of infection in the patient having diabetes mellitus. We have in sulfathiazole an effective agent for combating staphylococcal infections in general, but its efficacy in the management of urinary tract infections is limited by the factors outlined. Prophylactic use of this drug in small doses for patients with diabetes when bacteria are found in the urine in the absence of symptoms referable to the urinary tract may prevent the development of a serious infection with destruction of renal tissue.

Maintenance of the caloric intake is of particular importance in chronic infections. The insulin requirement is greatly increased in the face of infection and, as Wilder¹⁴ has pointed out, the patient may need insulin then even if he did not need it before. The maintenance of fluid intake at as high a level as possible is of great importance for the patient with diabetes complicated by renal infection and cannot be over-emphasized. When surgical intervention is necessary, local anesthesia is much to be preferred to any form of general anesthesia. The introduction of any factor which tends to cause dehydration increases the difficulty of controlling acidosis.

In the treatment of these infections, it is of the utmost importance to bear in mind that destruction of renal tissue must be prevented or stopped at the earliest possible moment. Parenchyma, once destroyed, cannot be replaced. Not only is the loss of renal tissue important in itself but there may also be serious consequences outside the kidney because of the production of vascular lesions in many organs.¹⁵

CONCLUSIONS

1. Asymptomatic urinary infections are much more frequent in patients with diabetes than in those without this condition.

2. The asymptomatic urinary infections in the diabetic state may lead to serious lesions of the kidneys. Necrosis of renal tissue extends rapidly, once the infection gains a foothold. It is increased in some cases by centripetal propagation of thrombi which form about the areas of infection.

3. A consideration of the end results of urinary tract infection in patients with diabetes emphasizes the importance of treating the infections before irreplaceable tissues have been destroyed.

ABSTRACT OF DISCUSSION

DR. THOMAS P. SHUPE, Cleveland: The clinician as well as the pathologist does not know much about the subject. That it occurs quite frequently in diabetes has been shown by Guenther, whom the authors mentioned, and that was brought out in 1937. The authors cited 1 case of a man aged 60 with no sugar in the urine and ascending urinary infection. He had a hydronephrosis and blockage by a large stone in the ureter. The kidney removed showed extensive papillary necrosis. On investigation the blood sugar showed an elevation of 170 to 200. Later, death and autopsy revealed the same necrosis on the other side. The difficulty with these cases has been that the diagnosis was made in reverse; that is, from the autopsy table back to the laboratory. The nondiabetic may show papillary necrosis, but nobody has reported such cases except in the advanced cases of carcinoma of the prostate and of the bladder. The pathologist making an autopsy on a patient with a dilated stomach and fatty degeneration of the liver, a yellow cranium and a firm brain should look for the papillary necrosis and other signs of diabetes. There is no doubt that the diabetic patient is subject to many hazards even if he has sugar in the urine. The diabetic patient without sugar in the urine is perhaps subject to a great many more hazards, and, next to the toes, perhaps the genitourinary system is the most vulnerable. The authors have shown in the slides the papillary necrosis which occurs in these cases. It is a question how much diagnostic and operative procedure should be done in these cases. I should think as little as possible. Whether a retrograde pyelogram is justifiable until the diabetes is well under control is another question; certainly no surgical procedures are except for unblocking of obstruction in the genitourinary tract. Another lesion that must be considered in this connection is the cord bladder with degeneration of the posterior columns due to diabetes. Of course, then one is going to have the residual urine with infection and the general debilitation of the patient. From the rapidly spreading infection which exists in these cases, I think it would be well in all cases of genitourinary infection and obstruction to investigate the level of the blood sugar as well as the blood urea, the nitrogen and the creatinine.

DR. ORVILLE T. BAILEY, Boston: In the general behavior of any infection there are two factors to be considered: One of these is the character of the organism concerned; the other is the state and character of the tissues attacked by the organism. In the infections which we have discussed here there is a striking instance of an unusual result from a familiar group of organisms. *Escherichia coli*, staphylococci and so on have produced extensive spreading necroses. We must search for the explanation of these lesions not in the nature of the organism but in the character of the tissues infected. Certainly the presence of diabetes is important in bringing about this result. Necrosis of the papillae, in spite of the amount of attention devoted to it in the literature, can hardly be regarded as an isolated lesion. It is a part of a necrotizing process which is demonstrable clinically, especially by the retrograde pyelogram, but does not represent the whole of the condition. By the time necrosis of the papilla is demonstrable the infection has already spread far up into the parenchyma. The unusual character of response to *Escherichia coli* is especially borne out in the third case presented here. The organism produced a massive infiltration of the tissues with gas, not only of the kidneys but of the perirenal tissues, and the necrotizing process led to complete destruction of both adrenal glands. The infection not only resulted in abscesses but in almost complete gangrene of both kidneys. Careful search of the main vessels failed to show any thrombi. On careful investigation of the small vessels there were thrombi beginning peripherally and extending centrally, thus progressively shutting off the blood supply, resulting in a spreading gangrene of the renal parenchyma.

THE MECHANISM OF DELAYED WOUND
HEALING IN THE PRESENCE
OF HYPOPROTEINEMIAJONATHAN E. RHOADS, M.D.
MAURICE T. FLIEGELMAN, M.D.

AND

LILLIAN M. PANZER, B.A.

PHILADELPHIA

During the past decade protein deficiency has been shown to have an important influence on many of the problems of clinical surgery. Gastrointestinal motility, especially gastric emptying after anastomosis of the stomach and jejunum, was shown to be profoundly

Fig. 1.—Biopsy specimen of wound in dog 511 taken seven days after the original incision. The serum protein concentration was 2.08 Gm. and the acacia level 3.52 Gm. per hundred cubic centimeters. (Reduced from a photomicrograph with a magnification of 300 diameters.)

retarded by protein depletion,¹ and it was shown that in certain instances "vicious circle" can be relieved by transfusion.² Goldschmidt, Vars and Ravdin³ demon-

strated that the protein balance of the body profoundly influences the vulnerability of the liver to chloroform. As a corollary to this principle, diets high in protein as well as carbohydrate were recommended in the treatment of patients with extensive hepatic disease.⁴ It is believed that such diets will also prove of great value in the preparation of the thyrotoxic patient for operation.

Fig. 2.—Biopsy specimen of wound in dog 42 taken seven days after the original incision. The serum protein concentration was 1.91 Gm. and the acacia concentration 2.38 Gm. per hundred cubic centimeters. (Reduced from a photomicrograph with a magnification of 300 diameters.)

The relation of hypoproteinemia to wound disruption was first demonstrated in the dog by Thompson, Ravdin and Frank⁵ in 1938. They showed that the hypoproteinemic dog is frequently incapable of normal fibroplasia. Another systemic factor interfering with wound healing is C avitaminosis. The importance of this factor was clearly demonstrated in the guinea pig by Lanman and Ingalls⁶ in 1937.

It has since been a matter of considerable interest to know whether the experimental data are of importance clinically. At the 1940 annual session of the American Medical Association, Hartzell, Winfield and Irvin⁷ reported on the serum protein and serum ascor-

bic acid levels of 20 patients with wound disruption. Hypoproteinemia was present in every patient, and the ascorbic acid level was low in all but 1. C. P. Rhoads⁸ has recently stated that in a group of patients

Fig. 3—Biopsy specimen of wound in dog 43 taken seven days after the original incision. The serum protein concentration was 1.99 Gm. and the acacia concentration 2.77 Gm. per hundred cubic centimeters (Reduced from a photomicrograph with a magnification of 300 diameters)

with wound disruption encountered at the Memorial Hospital, New York, hypoproteinemia has been present more frequently than C. avitaminosis. We have since had the opportunity of observing 2 patients with wound disruption in whom hypoproteinemia was present with a normal blood ascorbic acid level, and it is our impression that a protein deficit of sufficient magnitude to retard wound healing seriously is more common than a C. avitaminosis of sufficient severity to have an equally deleterious effect. Rhoads and Kasinskas⁹ more recently have shown that the plasma-depleted dog is slow to form bony callus after experimental fracture.

In the animals studied by Thompson and his associates the hypoproteinemia was induced by repeated plasmaphereses, the animals being maintained on a diet containing less than 1 per cent of protein. This diet was regarded as adequate with respect to all known vitamin and mineral requirements. The serum protein level was reduced gradually over a period of two to four weeks to edema levels (usually under 3.5 Gm. per hundred cubic centimeters). It is known, from the work of Whipple¹⁰ and others, that this procedure

depletes the labile protein stores of the body. It results also in a substantial reduction in the plasma volume. Ascites is frequent as well as edema of the extremities. The intraperitoneal tissues are waterlogged, as are the muscles of the abdominal wall. It is evident, therefore, that these dogs suffer in two important regards: (1) They have been for some time in negative nitrogen balance and have a general nutritional deficit of protein, and (2) their colloid osmotic pressure is seriously reduced, with a resultant disturbance in the relation between intravascular and interstitial fluid.

It is obvious that the formation of any new cells, such as fibroblasts, requires protein. Whether this protein would have to be derived from dietary protein or from the stores of labile protein or whether it could be derived from other fixed proteins or the products of their catabolism is uncertain. There is also the possibility that the disturbed osmotic relations in the hypoproteinemic dog might interfere with the utilization of available protein for the production of fibroblasts.

While it was not possible with the means at our disposal to investigate fully the intermediary metabolism of protein, it was possible to restore the osmotic properties of the plasma of the hypoproteinemic dog by the administration of acacia without contributing to the protein intake. Seven animals were prepared in which the protein levels were below 3.5 Gm. per hundred cubic

Fig. 4—Biopsy specimen of same wound as in figure 1 taken at fourteen days (Reduced from a photomicrograph with a magnification of 300 diameters)

centimeters but in which there was enough acacia circulating in the plasma to prevent any tendency toward edema. The concentration of acacia was maintained between 2 and 3.6 Gm. per hundred cubic centimeters.

Three methods were used in the preparation of the dogs. The first 2 were prepared by the repeated administration of acacia solution according to the method of Yuile and Knutti.¹¹ The observations of these authors that this procedure reduces the fibrinogen concentration and also reduces the serum protein concentration were fully confirmed. Their suggestion that the hemorrhagic tendency observed in some of these dogs might be due to a prothrombin deficiency was not completely substantiated. The prothrombin concentration was at times moderately reduced but not to a point low enough to explain the bleeding tendency without reference to some other factor. Whether there was any other factor, except the low fibrinogen level, we do not know.

Fig. 5.—Biopsy specimen of same wound as in figure 3 taken at fourteen days. (Reduced from a photomicrograph with a magnification of 300 diameters.)

The second method, employed on 2 dogs, was a modification of the procedure for total plasmapheresis described by Stanbury, Warweg and Amberson.¹² While the dog was bled from the femoral artery an infusion of erythrocytes suspended in a solution of acacia was given. The procedure was not carried as far as it had been in the experiments conducted by Stanbury and his associates.

The third method, employed on 3 dogs, consisted first in the preparation of hypoproteinemic dogs by the same technic used by Thompson, Ravdin and Frank.⁵ After the hypoproteinemia had been established the test

wounds were made and infusions of acacia begun. This procedure had the advantage of depleting the "labile" stores of protein of the animal as well as of reducing the plasma protein concentration. In all 7 dogs incisions

Fig. 7.—Scanty fibroplasia in plasma-depleted dog fourteen days after original incision. The incision is at the upper right. (Thompson, Ravdin and Frank.⁵)

Fig. 8.—Normal fibroplasia at seven days in a dog whose proteins had been restored by the administration of large amounts of lyophil serum. (Thompson, Ravdin, Rhoads and Frank.¹³)

were made by aseptic technic through the skin, the subcutaneous tissues, the rectus sheath and the rectus muscle on the right and the left sides. The incisions were approximately 2 inches (5 cm.) long.

11. Yuile, C. L., and Knutti, R. E.: Blood Plasma Proteins as Influenced by Intravenous Injection of Gum Acacia: Production of Chronic Hypoproteinemia, *J. Exper. Med.* 70: 605 (Dec.) 1939.

12. Stanbury, J. B.; Warweg, Edna, and Amberson, W. R.: Total Plasmapheresis, *Am. J. Physiol.* 117: 230 (Oct.) 1936.

The rectus sheath was closed on the right side with interrupted sutures of catgut and on the left side with interrupted sutures of silk. On both sides the edges of skin were approximated with interrupted sutures of silk, which were removed on the fifth day. Biopsy specimens were taken at right angles to the wound on the seventh

Fig. 9—Normal fibroplasia at fourteen days in a dog whose proteins had been restored by the administration of large amounts of lyophil serum (Thompson, Ravdin, Rhoads and Frank¹³)

and fourteenth days. All the wounds showed definite fibroplasia. Photomicrographs of specimens from the wounds of the last 3 dogs are shown (figs. 1 to 5). In comparison, photomicrographs from the paper of Thompson, Ravdin and Frank⁵ disclosing the absence of fibroplasia in hypoproteinemic dogs are shown (figs. 6 and 7), as well as photomicrographs from the paper of Thompson, Ravdin, Rhoads and Frank¹³ disclosing normal fibroplasia obtained in dogs whose hypoproteinemia had been corrected by the administration of large amounts of concentrated serum (figs. 8 and 9).

COMMENT

It is evident from these experiments that the formation of fibroblasts is not a function of the concentration of the serum proteins. In fact, in the last 3 animals which received acacia the protein concentration dropped from 3.67 to 1.91, from 3.55 to 1.99 and from 3.11 to 2.08 Gm. per hundred cubic centimeters, respectively, within seven days after the administration of the first infusion of acacia solution. One of the animals had

had a decubitus ulcer near the ankle for a week prior to the administration of acacia; during this time it had shown no tendency to heal. Within twenty-four hours after the acacia was administered this ulcer was covered with a dry scab, and healing proceeded rapidly during the next seven days. Another animal had an open sore which had persisted for a week. This also had practically healed within a week after the administration of acacia had been started. The following hypotheses have been suggested in explanation of the effect of the acacia:

1. The relation of hypoproteinemia to wound healing is mainly on an osmotic basis. The acacia corrects the low colloid osmotic pressure of the serum, with the result that fibroplasia occurs.

2. The relation of hypoproteinemia to wound healing is mainly on a nutritional basis, but the administration of acacia makes it possible for more protein to be withdrawn from the plasma for tissue-building purposes.

The liver appears to be full of acacia on histologic examination (fig. 10). The acacia may reduce the affinity of the liver for labile protein and thus make available for tissue repair a larger proportion of the small amount of protein in the diet and perhaps a larger

Fig. 10—Section of liver of dog 511 after administration of 1,500 cc. of 6 per cent acacia solution in a two week period

proportion of the products of normal protein catabolism. It is not possible at present to decide which of these hypotheses is correct or whether both are important.

CONCLUSIONS

Fibroplasia occurs in the hypoproteinemic animal if ample amounts of acacia are given intravenously to maintain the colloid osmotic pressure of the plasma.

13. Thompson, W. D; Ravdin, I. S; Rhoads, J. E., and Frank, I. L. Use of Lyophil Plasma in Correction of Hypoproteinemia and Prevention of Wound Disruption, Arch Surg. 36: 509 (March) 1938

This occurs even if chronic hypoproteinemia is produced so as to deplete the stores of labile proteins. It is evident that the failure of fibroplasia in the hypoproteinemic animal is not directly a function of the concentration of the serum proteins. Acacia solution is not recommended in the treatment of hypoproteinemia in patients.

ABSTRACT OF DISCUSSION

DR. CHARLES G. JOHNSTON, Detroit: Dr. Ravdin and Dr. Rhoads have pointed out the effect of low serum protein on wound healing and the importance of nutrition in surgical patients. Hartzell and his associates have pointed out the relationships of vitamin C to wound healing in patients and in experimental animals. These contributions have made us aware of the importance of nutrition for surgical patients. It is significant that, in the cases of wound disruption which we have studied, the majority have been in patients who have had gastric or duodenal lesions, chiefly ulcer patients, and a majority of them have been on diets. We have recognized definitely, and Dr. Rhoads has intimated, that serum protein determinations do not necessarily mean that we are measuring the ability of the organism to mobilize the protein or to utilize it. More to the point is the fact that plasma vitamin C determinations give little if any information regarding the vitamin C content of the cellular elements. The paper of Dr. Rhoads and his co-workers has afforded proof that the colloidal osmotic pressure is of importance in wound healing. However, I have noted in patients in whom disruption has occurred that the serum protein was only in rare instances low enough to be considered below an edema level. I wish I could explain why an animal with low serum protein might be restored to normal wound healing after the administration of acacia. The data presented do not intimate that in patients who have difficulties with wound healing one should recommend acacia infusions. I prefer Dr. Rhoads's second explanation of the way in which acacia assists, namely the mobilization of protein for utilization. Wound healing is not a simple phenomenon but depends on many factors. It cannot be explained on any one basis, but all factors must be brought into play. As far as nutrition is concerned, serum protein and vitamin C alone are not the entire answer. We cannot ascribe to any one factor exclusive importance in the healing of wounds.

DR. JONATHAN E. RHOADS, Philadelphia: I want to thank Dr. Johnston for emphasizing that acacia is not a suitable agent to use in patients with hypoproteinemia with the idea of improving their wound healing. To maintain concentrations of acacia of 2 or 3 Gm. per hundred cubic centimeters in the blood of these dogs for two weeks, it was necessary to administer a volume of 6 per cent acacia, equivalent to approximately three times the normal plasma volume. You saw what changes were induced in the liver by this amount of acacia, and as long as it is so easy now to get plasma for transfusion it seems no longer justifiable to use acacia in treating human patients.

The Specialty Boards.—There is another criticism of the special boards as at present constituted, which is that they lay too much emphasis on specialization. In an entirely laudable effort to ensure that every doctor who presumes to call himself a specialist shall be entitled by reason of his training to do so, they have made it well nigh impossible for a man to obtain a solid general foundation. This is what happens. The board demands first a year of general work as an intern or in practice, followed by three years of work at the specialty, whichever it may be. This may be done as two years as a hospital resident and one year in practice as assistant to a senior man, or the whole three years may be spent in hospital, though not many hospitals have facilities for a full three years residency. However, this is what is considered the optimum, and these requirements, which in the early days of the boards—and they are still quite young—had to be elastic to allow of the established men taking them, will shortly become absolute.—Atkinson, Miles: *Behind the Mask of Medicine*, Charles Scribner's Sons, 1941.

SOME MENTAL MECHANISMS IN ALCOHOLISM

FRANK GARM NORBURY, M.D.

JACKSONVILLE, ILL.

Many approaches and many methods are and have been in use in the study of alcoholism—social, religious and economic as well as scientific. Special societies ranging from the Association for the Study of Alcoholism, with its objective approach, to Alcoholics Anonymous, with its emotional revivalistic urge, are engaged in this problem. Medical investigation likewise has used different technics. Biochemical, physiologic and experimental psychologic research are productive of information. Neuropsychiatry has used various methods from restraint and seclusion to psychoanalysis and attempts at personality education or reeducation in its efforts. This paper deals with a study of alcoholic but otherwise successful persons with whom such attempts were made and some of the mental mechanisms that were found during the course of these attempts.

The source material may be called selected in that it is composed of 105 patients representing 164 of the last 2,000 admissions to a private psychiatric sanatorium. This of itself rules out marginal and indigent economic groups, which differs from Wittman's series.¹ The diagnosis for purposes of classification was "without psychosis, alcoholism." This paper is not as inclusive as the papers of Wall² but conforms more to Karpman's³ remarks in discussion of the former's paper.

Business and professional men made up the greater part of the group and a number of farmers, a few representatives of the arts, a few housewives and career women completed the group. Many were college graduates. The general intelligence level was adult or superior adult. In other words, these persons were considered successful in their sphere whether metropolitan, small town or rural. An early question asked was how they came to be alcoholic. As more contacts were made and more similarity in reaction types was noted, the next problem was how to combat the difficulties that these persons had and how to help them. Out of this experience have come some impressions outlined hereafter.

Most patients entered under the influence of alcohol or with a history of recent overindulgence. An old conception of three stages in management has been followed: During the first stage, while care for the physical features is carried on, some idea of the patient's underlying make-up, freed by alcohol from inhibitions normally present, may be ascertained. During the second stage, when indirect toxic features are still present, when remorse, conscience, apprehension over the effect of disability on business, professional, social or family situation exist, conversations may reveal some conflicts that lead to escape through alcohol. The patient is still shaky emotionally even if not physically. So the trend of conversation runs in that direction with various inferences and sequestrations that may be brought out.

Read before the Section on Nervous and Mental Diseases at the Ninety-Second Annual Session of the American Medical Association, Cleveland, June 4, 1941.

Persons in this group are sensitive and want at this time sympathy and a justification or rationalization for their drinking, even though they may not ordinarily show it. Recognition of this part of their make-up permits them to unburden. It should be stated here

TABLE 1.—*Characteristics Studied in One Hundred and Five Alcoholic Patients Without Psychosis*

Economic adjustment	Homosexualism	Pathologic response
Success in occupation	Heterosexualism	to alcohol
Intellectual level	Filial overdependence	Deterioration
Social attributes	Emancipation	Superficiality
Affective response	Forefulness	Oral traits
Adaptability	Perseverance	Reaction to mastur-
Activity	Aggressiveness	bation
Extrovert-Introvert	Feeling of inferiority	Inflexibility
Gregariousness	Feeling of guilt	Serupulosity
Solitary drinking	Sensitivity	Consistency
Communicativeness	Mood: Cheerful	Apprehension
Responsibility, general	Depressed	Suspiciousness
Responsibility, alcohol	Irritable	Preoccupation
Self control	Hypochondriasis	Day dreaming
Attitude to habit	Narcissism	Depersonalization
Sexual adjustment	Anorexia	Alcoholism in family
Marital adjustment	Sleep disorder	

that no attempt to secure transference is made in this stage when emotional factors predominate or in the third stage when the person has resumed the habitual type of response. During the third stage, when the person feels well physically, is outwardly at least settled down and is engaging in activities with associates, more objective conversations based on history and information acquired in earlier observations can be carried on.

Forty-eight characteristics combined from several sources⁴ were used, as shown in table 1. The information was assembled from histories, self estimates, notes and personal observations. Analysis of these characteristics naturally depends on the approach of the analyzer. An attempt has been made to use as nearly an objective or laboratory approach as possible. No brief is held for any school of psychiatric thought save a study of the total personality. Such a study covers many classifications not mentioned, but even then headings were difficult to find for some outstanding expressions of individual statements. Predominating characteristics are shown in table 2.

It is obvious that the patients in this series were not able to adjust satisfactorily or they would not have come under observation. Nevertheless, as indicated previously, their economic adjustment was such that they or their families could take care of hospitalization; 90 of the 105 could be definitely classed as successful in their occupations; 88 were counted as having satisfactory social attributes; 68 showed good affective response. Adaptability was fairly high in that 63 had a plus rating, while activity was higher than most characteristics with 97 persons marked positively. A corollary to these figures might be found in an attempt at extrovert-introvert typing, with 79 classed in the former, 22 in the latter and 4 in the unclassified grouping. It is recognized that this is an artificial grouping, as it is difficult to classify many persons as pure extrovert or introvert. Gregariousness ran ahead of the extrovert grouping; 90 persons were noted as having that tendency. It is difficult to assay this in the light of the finding that 95 were counted as solitary drinkers. I have taken the position, however, that the person who drinks at home, in his club, hotel or tavern and communes with one person, whether spouse, waiter or barkeeper, is still a solitary drinker in the psychologic

sense. The communicativeness which 94 people showed raises the question of whether the attempt of the alcoholic to fraternize does not represent a tendency of the introvert to break through natural inhibitions toward social contact or perhaps social contact with a superior group. One must always consider, in evaluating the foregoing reactions, the effect of alcohol in loosening acquired inhibitions, thus revealing latent active personality traits.

General responsibility ran high, as would be expected in this group, with 80 accepting it. Responsibility as to alcohol, self control with respect to it and attitude toward the habit were low, as would also be expected, with 7, 3 and 25 persons respectively showing anything at all of a constructive reaction. This last category is an important one from the point of therapy. It is obvious that it is only through attempting to develop a positive attitude in the patient that anything is going to be accomplished. The ways and means of developing it through various psychiatric technics are less important than the imperative need for it.

Any arrangement of personality studies must include sexual adjustments in their direct and indirect relationships. Sixty-three were considered as having made sexual adjustment, 30 as not having done so and 12 were questionable. Ninety-three were or had been married. Fifty-two had made a satisfactory marital adjustment, 32 had not, 3 had a plus or minus rating and 6 had a questionable one. Relatively few patients showed overt homosexual tendencies. Not many showed the latent tendencies frequently referred to in alcoholism with expressions in parties, groups and the like. Perverse sexual tendencies were not frequently found. The chaotic sexuality referred to by Rosanoff⁵ was evident and, on a percentage basis, even outstanding. Marital maladjustments past and present were frequent. Resort to alcohol in the hope of sexual stimulation for incapacity was rare, though impotence was not infrequent. Most of the marital difficulties arose out of a conflict over the patient's habit. Where they did occur in this group they were mostly social and domestic, which is part of the chaotic sexuality. Conflict on an economic basis over failure to provide occurred only twice.

Filial dependence and/or emancipation therefrom may be considered from the psychoanalytic approach or it may be taken as part of the growing up process.

Records of 43 indicated filial overdependence, while 68 showed emancipation from it. Twenty-nine of the dependent ones failed to develop freedom. Undoubtedly there were others as well in whom the overdependence was latent if not manifest. Escape through alcohol to a false feeling of emancipation was shown frequently in resentment toward parents in expressions

such as drinking being one way of showing independence. While outwardly conforming at most times, the inability to be normally independent led them to desire it abnormally—hence alcohol.

Forcefulness was not an outstanding characteristic. Less than half received such a rating. Genuinely forceful persons would probably not have become patients. Perseverance, chiefly in regard to occupation and perhaps therefore a compensation reaction, was noted in 68. Many of the same persons who lacked forcefulness and perseverance showed feelings of inferiority, which is compatible. However aggressiveness, which is often used to cover a feeling of inferiority, was more frequently noted in the ratio of 52 to 41 of the 105 persons, so undoubtedly some of that category were missed. Outward manifestations of sensitivity which were the criteria used were likewise not frequent, being checked in 40, though considering other characteristics and inadvertent expressions used in the discussion of other features this number probably is actually higher.

Mood levels considered when not under the influence of alcohol and taken from the statements of the patients and relatives gave 40 habitually cheerful, 27 depressed and 38 irritable. Almost all of the depressed and some of the irritable showed sufficient self anxiety to be classed as hypochondriacal. Some of the outwardly cheerful likewise evidenced hypochondriasis, which would here be classed as undue self interest, a form of narcissism. Manifest signs of the latter were much less frequent.

Psychosomatic features were not considered much in this study, as primary physical phases were purposely omitted. Anorexia was present in 48, a little less than half. Sleep disorder showed a high frequency, 81 evincing it. A pathologic response to alcohol in either physical or psychic sense was naturally present in all. Deterioration was thought to be present in 4 and enough indication was found to be questioned in 29. It would probably be observed more in the finer emotional range in this group.

One trait that has long been recognized as an integral part of alcoholic persons is superficiality. That applies as much for this group of professional and business people, socially adequate, with in general higher than average intellectual capacity, as it does for a group in a different social, economic or intellectual level. Ninety of the 105 were classed so. It is believed that in the present stage of knowledge about overindulgence in alcohol the most important question is "Why?" Why are these people superficial? Why, when they "get a thirst" do family, business, social responsibilities sit lightly? Why do entreaties of relatives, partners, friends do no good? The answer to these questions is well known to physicians. It embraces desire to conform, ambition to be able to drink socially, to be a man among men. All these are adolescent types of reaction indicative of emotional immaturity. They fit in with characteristics presented. So far as capacity, general activity and affect are concerned, most of these patients appear to fall into a cyclothymic category with associated mental mechanisms. Overdependence, feelings of inferiority and superficiality are more consistent with the schizoid tendency, with the last of these traits being predominant. The material offered here agrees with the opinion of many that the reason for alcoholism is to be found in the personality of the individual. As Kraines⁶ says, "The addiction to alcohol is determined

by the internal drive and not by the simple taking of alcohol." While one hesitates to make a didactic statement, the material seems to emphasize a lack of maturity and a difficulty in expression and accomplishment along some lines, chiefly in the emotional field of consciousness.

Parental attitudes have much to do with personality responses in the offspring. It would be far fetched as well as unfair to blame parents for development of alcoholic tendencies in children after the latter have been away perhaps for years. Nevertheless, in alcoholism and in other psychiatric disorders, notably schizophrenia, Williams'⁷ description of "innocent yet dangerous parents" comes to mind with the carry-over into adult life of adolescent reactions affecting both parent and child, the latter even when grown up in other ways.

Therapeutic attempts in this group have been direct and educational. Since the disturbance is emotional, I believe with Miles⁸ that the emotional component in treatment should be interjected as little as possible. The fact that these patients have in the main accepted business and social responsibilities is discussed with them. Various incapacities, maladjustments and conflicts are explained. Attempts at development of personal responsibility are then taken up. There is nothing new in this approach. It is one of the recognized forms of psychotherapy, considered outmoded by some, but in the light of the general intelligence level and general responsibility of this group it appears useful.

It is not possible to make an analysis of results in the same way that has been done for the material, for follow-up reports have not been made in many instances. Records indicate many notable failures, some worth while successes. It is felt that the characteristics and mental mechanisms described here in the study of individual patients have much to do with the personality reactions of the failures. A corollary to this may be that recognition on the part of the intelligent patient and a constructive attitude of personal responsibility developed through direct psychotherapeutic approach has had something to do with the successes.

ABSTRACT OF DISCUSSION

DR. LLOYD H. ZIEGLER, Wauwatosa, Wis.: As physicians, we are likely to focus our attention on a few medical aspects of a person which are the basis for calling him a patient. Dr. Norbury has made a broader survey of the qualities of human nature in a group of reasonably successful and capable so-called nonpsychotic alcoholic patients. It would have been valuable to have available an equal number of nonalcoholic persons from similar strata of life for comparison. Had he studied a control group, some of the qualities of the alcoholic addicts that now seem significant would doubtless overlap with the controls to rob them of their seeming relationship to alcoholism. His patients were responsible about most things except themselves and their relationship to alcohol. One can see this in the diabetic patient who refuses to follow a diet restriction, in persons who hear the morning alarm clock but who refuse to heed it and so get to appointments late, in persons who violate the fishing or hunting laws or in automobile drivers who blame everything except themselves for accidents. This attribute is not limited to alcoholic addicts by any means. The fact remains that alcohol never of itself runs into any one's mouth. A definite person assumes responsibility for seeking it out; he uses his own right hand in lifting it to his mouth; he swallows it. These acts he performs and for them he must assume responsibility. What happens after this is often mixed up with excuses but not with responsibility. There is a dif-

ference. The alcoholic addict can ever point to the milieu of society which makes light of the affair. Judges of the court too who should be expert in placing responsibility have been known to use drinking as an excuse for leniency toward the results of the misuse of alcohol. Alcoholism is merely a name applied to the behavior of a definite person who thinks he can drink or let it alone but always drinks. This is a serious breach of responsibility to himself and often to his family. He becomes ex-alcoholic when he controls his irresponsibilities. Dr. Norbury's observation of superficiality interested me. Alcoholic addicts are often active, on the go, and may be bored by serious and sustained effort. They have seemed not quite grown up, living the part of youthful actors in a play world in which they get on splendidly together. There is great demand for the person who is witty and friendly, has warmth of personality, but who is not a deep thinker. Dr. Norbury's interest in these patients has been so broad that he has the armamentarium for succeeding where others might fail.

DR. G. WILSE ROBINSON JR., Kansas City, Mo.: Before the American Psychiatric Association in Richmond last month, Dr. Seligman presented a similar analysis. In Dr. Norbury's series such things as economic adjustment, success in occupation, intellectual level plus and social attributes plus are found in the majority of his patients. These are what we call normal characteristics. I have made this observation in my own cases time after time. I believe the problem as to why most economically successful alcoholic addicts drink is a rather simple one to state but a hard one to solve. He drinks for the same reason that the president of the bank, the circuit judge and the roost-about drinks: in order to have fun with other people or to relax. I believe that all alcoholic addicts start out as social drinkers, and it is only after alcoholism has become a problem that they attempt to hide it. Temptation to drink is almost universal. In certain social groups alcohol is served at every social function, and I have had many alcoholic patients tell me they get along fine until they attend some social event where liquor is served. I have had fellows tell me they have gone through the event and then the next day started to drink. From time to time it really becomes overwhelming, or their nervous fatigue becomes so intense that they need a sedative to produce relaxation. After they have started a drinking experience they cannot stop, and then they may drink in a solitary manner, hoping to hide it. I feel that the major problem with regard to the alcoholic addict is that he is no longer able to control alcohol. For many years he has been drinking socially. Suddenly he finds he cannot. The known diabetic patient is not tempted with sugar. Everybody understands why he cannot use sugar. However, the known alcoholic addict is not only served liquor but he is usually urged to drink for old times' sake. The strain on resistance is too much on many occasions. The problem of alcoholism will not be solved until we have found some way to make it possible for the alcoholic addict to drink again as he used to drink. I believe the problem is more physiologic than psychologic. My series includes a cross section of the social and economic life of Kansas City. It includes successes and failures, professional men and laborers, rich and poor, social registrants and bums. The only universal motif that I have been able to find is an inability to drink like other men. Certain thinkers may consider that psychologic. I consider it a physiologic problem, and I believe that the pathologic, physiologic and pharmacologic problem must be solved as well as the possible psychologic problems before we can find a solution to the problem of alcoholism.

DR. R. V. SELIGER, Baltimore: I congratulate Dr. Norbury on his fine paper on the personality characteristics of the alcoholic addict. I found that 50 per cent of the alcoholic addicts were extroverts and 50 per cent were introverts. As far as family inheritance is concerned, I think that one out of three of our group had a family background of alcoholism. I feel that the social drinker can handle alcohol so that it does not interfere with his important life activities, while a chronic alcoholic addict is handled by alcohol so that it does interfere with his important life activities. I do not feel that a chronic alcoholic addict can ever again drink. The only way for help and guidance and cure is total abstinence for life. Once a pathologic drinker, a person can never be a social drinker. There are about seven important factors in the successful rehabilitation of the alcoholic

addict. Among these are the personality of the psychiatrist and the careful selection of patients. The patient has to have average intelligence or better. He has to have some emotional maturity in his make-up. His nervous system has to be undamaged at the time of treatment, and he must want treatment. You cannot treat a patient against his will. There has to be some psychiatric approach to find out what the mechanism is behind his drinking, if any, whether you go through the psycho-analytic approach or take the psychobiologic approach or any other approach. Then there must be a long period of rehabilitation, training and regulation of the patient's emotional life. Along with these there is a certain suggestive factor in which the patient knows that the doctor is interested inherently in alcoholic addicts, that he has helped others, and the patient sees by contact with former patients that alcoholic addicts can be helped. The follow-up for the rest of his life is important, either by correspondence or by visits. Finally it is my feeling that whether one considers that alcoholism is evidence of an escape mechanism or a neurosis or a psychosis or is evidence of latent or overt homosexuality or of a tendency to self destruction, one must realize that the situation is an individual psychobiologic personality reaction to life and life situations plus habit formation both in the emotional field and to the drug.

DR. F. GARM NORBURY, Jacksonville, Ill.: There are many ramifications of this subject. It was my purpose just to bring out certain features that had interested me in a personality study. I am inclined to agree with Dr. Seliger that the alcoholic addict cannot drink again. There are both psychologic and I think biochemical factors in that. If one can think of sensitization, the person who has used alcohol in the past is not only psychologically but I believe in a certain sense biochemically sensitized, at least in that it produces a catalytic type of explosive reaction; but that is rather outside the discussion of this particular paper.

STUDIES IN NICOTINIC ACID METABOLISM

V. A TEST FOR NICOTINIC ACID DEFICIENCY IN MAN

WILLIAM A. PERLZWEIG, Ph.D.

HERBERT P. SARETT, M.S.

AND

LESTER H. MARGOLIS, M.D.

WITH THE TECHNICAL ASSISTANCE OF MOLLY STENHOUSE, A.B., AND FRANCES SPILMAN, A.B.

DURHAM, N. C.

It has not been possible to demonstrate nicotinic acid deficiency in man by the determination of either the blood level of nicotinic acid¹ or the level of urinary excretion.² The test described here is based on the level of excretion of nicotinic acid and trigonelline after a dose of nicotinamide.

In dogs maintained on a diet low in nicotinic acid it has been shown that a dose of nicotinic acid is largely retained.³ After the dogs were well saturated by a high intake of nicotinic acid, most of the test dose of nicotinic acid was found in the urine as acid hydrolyzable nicotinic acid derivatives and trigonelline. This principle was applied to man in the following way:

Twenty-four normal adults were instructed to omit for three days coffee, all leguminous vegetables and

nuts (all of which contain trigonelline) from their otherwise adequate diets. On the evening of the second day the subjects voided just before dinner and discarded the urine. All urine, including that voided on rising, was collected until the next morning and preserved with

Distribution of extra excretion of total nicotinic acid after 500 mg. of nicotinamide (mg. in twelve hours).

toluene. Each subject ingested with the dinner 500 mg. of nicotinamide and again collected all urines until the next morning. The nicotinamide was administered intravenously to some of the patients as described later. No untoward or disagreeable reactions developed in any of the subjects after the oral or intravenous administration of 500 mg. of nicotinamide.⁴ The control and test urines were analyzed for the acid hydrolyzable nicotinic acid derivatives and for trigonelline by the method previously published.⁵

In addition to the 24 normal subjects the test was applied also to two other groups, the first consisting of 53 young men (aged 16 to 24) as they were admitted to a local National Youth Administration camp for the purpose of physical upbuilding by means of diet and exercise. This group consisted of underweight and undernourished boys, physically under par, with or without correctable defects but capable of physical work. There were no cases of organic or infectious disorders.⁶ The boys all came from the lower economic levels of the local population, as did the subjects of the next group of hospital patients.

Sixty-three patients, unselected as to nutritional status, type or duration of disease or age, were also subjected to this test. Of this group 50 represented every patient, without exception, who was admitted to a male public medical ward of Duke Hospital over a five week period. The other 13 (6 men and 7 women) were recently admitted medical patients taken at random. The tests were started on all of these patients within two days of their admission to the hospital while they were on the regular ward diet. They were all acutely or chronically ill with the large variety of diseases found in a public medical ward. Apart from 1 case of partly treated pellagra and 4 cases of frankly

characterized nutritional deficiency, the incidence of symptoms of general malnutrition such as loss of weight, anorexia and secondary anemia was relatively high in this group, being partly due to its low economic level and partly inherent in the clinical conditions which they presented.

A comparison of the findings in these two groups with the group of normal subjects is shown in the accompanying table and chart.

It will be observed that no significant differences in the nicotinic acid excretion were found in the control urines of the three groups. However, marked differences in levels of excretion of these groups appeared in the urines following the ingestion of 500 mg. of nicotinamide. These differences were found almost entirely in the trigonelline fraction of the urine. This explains the results of Briggs,⁷ who determined only acid hydrolyzable nicotinic acid derivatives and not trigonelline and was therefore unable to find differences between normal and deficient subjects. The extra total nicotinic acid (including trigonelline) excreted after the test dose averaged 90 mg. for normal persons, 63 mg. for NYA subjects and 41 mg. for hospital patients.

The distribution of individual value for the extra total nicotinic acid after the test dose is shown in the chart. All of the normal subjects gave values above 50 mg. and 84 per cent were above 75 mg., while among the patients only 11 per cent were above 75 mg. and 54 per cent were below 50 mg. The NYA group occupied an intermediate position between these two extremes.

The question of the completeness of absorption of the nicotinamide arose, and it was found that in 4 normal subjects the results obtained after intravenous and oral administration of the test doses, given several days apart, agreed very well. In 12 of the patients in whom there were symptoms of gastrointestinal or liver disease the amide was administered intravenously and the test was repeated orally one to four days later. With the exception of 1 subject in whom the oral test was con-

SUMMARY

The majority of hospital patients admitted to a general medical ward excreted in twelve to fourteen hours much less of a large dose of nicotinamide than normal persons. A group of undernourished youths excreted an intermediate amount after the same dose. The procedure described may serve as a test for nicotinic acid deficiency in man.

UNCOMPLICATED FRACTURES OF RIBS AND MAJOR INJURIES OF THE CHEST WALL

TREATMENT BY INFILTRATION WITH
LOCAL ANESTHETIC

PAUL H. HARMON, PH.D., M.D.

DAN R. BAKER, M.D.

AND

ROBERT D. KORNEGAY, M.D.

SAYRE, PA.

The usual attitude of the physician about fractures of the ribs is well summarized by the following quotation, taken from a current textbook on the treatment of fractures:¹ "Fractures of the ribs in themselves are not of much moment, and it is only their complications that make them important." The frequency of fractures of the ribs, together with the relative effectiveness of treatment afforded by wide hemicircumferential strapping of the chest, has resulted in widespread acceptance of this method of treatment. Whatever discomfort arises has been passed over as being "part of the treatment." However, therapeutic procedures should be made as agreeable to the patient as possible and the course of convalescence, even from minor injuries, free from pain and complications. In a recent authoritative symposium on fractures² the only method of treating fractures of the ribs given was strapping of the chest with adhesive tape.

Our experiences with the treatment of sprains, marginal fractures and painful myofascial disorders with procaine hydrochloride have led us to apply this method to other painful conditions. Investigators³ who have had the opportunity to witness the shorter and milder course of patients suffering from the acute traumatic conditions mentioned have advocated this method as the treatment of choice. At first we used it hesitantly on patients who suffered only pain from local and isolated fractures of ribs, but later we extended it, with the same immediate relief from pain and general alleviation of the course of convalescence, to patients with the major varieties of injuries to the chest that are described in detail later in this paper. While the results of treatment with procaine hydrochloride alone were satisfactory, the adoption of a double solution containing 0.5 per cent procaine hydrochloride and 0.1 per cent

eucopeine dihydrochloride (isoamylhydrocypreine dihydrochloride), to which epinephrine hydrochloride (10 drops per hundred cubic centimeters) was added, gave more prolonged primary anesthesia (three or four hours, as compared to one-half to one hour). This double solution is now used routinely in treating thoracic injuries at the Guthrie Clinic and Robert Packer Hospital.

The advantages of the injection treatment for fractures of ribs as compared with the immobilization treatment are that (1) pain is immediately abolished, because of the removal of pleural and local afferent sensations; (2) the vital capacity and the tidal air remain at a more normal level; (3) excessive coughing due to pleural irritation is diminished; (4) as a result, the use of general sedatives and cough mixtures is lessened or made entirely unnecessary, and (5) the injection is a minor procedure that can be carried out in the office. The only drawbacks are (1) the danger of infection, which is minimal with adequate aseptic technic (infection did not occur in any of our cases) and (2) the psychic disadvantage with persons who "do not like injection treatments." The only absolute contraindications are (1) known hypersensitivity to procaine or epinephrine hydrochloride and/or sensitivity to the quinine series of drugs (minor untoward reactions can be abolished by giving sodium amytal in doses of 1½ to 3 grains [0.09 to 0.18 Gm.] one hour before injection) and (2) a dirty or infected open wound in the skin that cannot be blocked off from the field of injection.

On reviewing the literature, we found that Zoppi⁴ has been the only author to recommend local infiltration of procaine hydrochloride for fractures of the ribs. In his article the daily infiltration of the analgesic was recommended. A number of articles have given supporting evidence to the effectiveness of regional nerve block in both simple and complicated injuries to the chest. Alcoholization of the intercostal nerves has been advocated by Latteri,⁵ Rabboni⁶ and Grieco,⁷ the method having been originated for the control of pain from tuberculous pleuritis. In this country only Rovenstine and Byrd⁸ have utilized intercostal regional anesthesia for analgesia in cases of extensive thoracic injuries. These authors expressed the belief that the method lessens the mortality, contributes greatly to the patient's comfort and is important as a prophylactic agent against respiratory infection.

MANAGEMENT

After the diagnosis is made and the site of the fracture accurately localized by roentgenograms, the patient is placed on a table with the site of fracture in a prominent and accessible position. A mark is placed on the skin with a solution of gentian violet, a silver nitrate stick or some other coloring agent that can be readily distinguished from the cutaneous disinfectant. The surrounding area is prepared with half strength tincture of iodine and draped with sterile towels. For convenience, in our clinic a standardized tray setup, containing syringes, needles and the solution to be injected, is prepared on the operating floor and transported to the

outpatient clinic or to the bedside. The solutions of procaine hydrochloride and eucupine dihydrochloride are sterilized separately in 1 per cent strength and mixed by diluting with physiologic solution of sodium chloride to obtain a final concentration of 0.5 per cent of the former and 0.1 per cent of the latter. Epinephrine hydrochloride solution (1:1,000) is then dropped into this mixture. A wheal is raised over the proposed site of injection, 1 cc. of solution is placed deeply in the subcutaneous tissues and 2 or 3 cc. of solution is infiltrated directly into the site of fracture. If this site and its surrounding hematoma cannot be directly entered or identified with the tip of the needle, 4 to 6 cc. of solution is placed in the surrounding tissues. With fractures above and including the third rib and with posterior fractures, especially those covered by the scapula and its mesial muscular attachments, it is difficult to make an injection directly into the site of fracture. Elsewhere localized tenderness and crepitus will serve as a guide to accurate deep placement of the needle. Single fractures in many ribs, multiple fractures in the same rib,

In addition to mentioning the cases of minor fractures of ribs we wish to illustrate the use of infiltration with local anesthetic for major injuries to the chest wall by the following case reports.

REPORT OF CASES

CASE 1.—*Open operative excision of protruding ends of ribs that had punctured the pleura; subsequent use of procaine hydrochloride-eucupine dihydrochloride solution to relieve pain in the chest from multiple fractures of ribs.*

C. F., a man aged 39, received a severe injury to the chest by being stepped on by a horse. When examined shortly after the injury had taken place he had pain along the whole right side of the chest. He was dyspneic and was in mild shock. Examination revealed dullness of the chest up to the seventh rib and exquisite tenderness in the right posterior scapular line. Roentgenographic examination revealed fractures of the right second to eleventh ribs inclusive, which were on the average 9 cm. from the costovertebral junction (figs. 1, 2 and 3).

On admission, the blood pressure was 116 systolic and 70 diastolic. The blood contained 3,400,000 red cells and 16,000 white cells per cubic millimeter. Since roentgenograms of

Fig. 1.—The chest in case 1 on the day of injury. Open operation was performed to excise sharp ends of ribs that had lacerated the costal wall, including the pleura. The arrows indicate the free fragments at the sites of fracture of the fourth and fifth ribs.

Fig. 2.—The chest in case 1 seventeen days after operation. Note the fluid level and the shift of the costal wall after excision of fragments of the fifth and sixth ribs.

Fig. 3.—The chest in case 1 two months after injury. The right side had practically cleared.

extensive injuries to the thoracic wall, mild to moderate shock and the presence of emphysema instead of being contraindications are, indeed, indications for use of the method. A small gauze dressing or a small cotton or gauze pledget soaked with collodion serves as a temporary dressing. Often one injection suffices, but in 8 (25 per cent) of the 32 cases of minor fractures covered in this report it was necessary to perform another injection at the site of fracture in one to four days. In no instance was a third injection necessary. Relief from pain is difficult to estimate and is impossible to measure exactly, but the normal response from the patient was that he was "comfortable," being immediately relieved from pain and only "slightly uncomfortable" for two to five additional days, with only an occasional pain on sudden positional change for two more weeks. The average period of disability (until the patient returned to his former occupation, usually light manual labor) was four and two-tenths days for the 32 patients. Twelve with fracture of a single rib returned to work immediately after treatment and were not "disabled." The 32 patients were given entirely ambulatory treatment.

the chest showed central displacement of the right fifth rib into the chest wall and through the pleura, it was deemed necessary to examine this rib at open operation.

Accordingly this was done, with infiltration anesthesia with procaine hydrochloride. The costal wall from the third to the seventh ribs was bared through a posterior horizontal incision which allowed the scapula to be pulled laterally. The mesial end of the right fifth rib was found to have perforated the pleura. One-half inch was resected from both the mesial and the lateral ends of the fractured fifth and sixth ribs, the pleural wound closed en bloc with the adjacent intercostal muscles, the rhomboid muscles reapproximated and the wound closed. Physiologic solution of sodium chloride was administered intravenously throughout the operation, which was well tolerated by the patient. The blood pressure at the termination of the operation was 100 systolic and 74 diastolic. Into each of the remaining fractures, not visualized at operation, 3 cc. of a 1 per cent solution of procaine hydrochloride was injected. The patient returned to the ward less dyspneic and breathing without pain in the chest. The vital capacity (normal, 4.4 liters) prior to operation was only 1,200 cc. Immediately after operation it rose to 1,600 cc.

On the morning of the following day the patient was fairly comfortable, but pain in the chest increased and the respiratory rate increased from 28 to 40. He was placed in an oxygen

tent sixteen hours after operation. Throughout this day the blood pressure was well maintained and the red blood cell count remained at 3,900,000 per cubic millimeter. In spite of the use of the oxygen tent, the patient became more dyspneic on the third postoperative day, and the slight cough which he had had on the second day increased in annoyance and severity. The cough was not productive, and the patient suffered extreme

Preoperative and Postoperative Estimation of Vital Capacity After Injection Treatment for Fractures of Ribs and Injuries to the Chest

Case	Normal, Liters	Pilot to Injection, Liters	Immediately After Injection, Liters	Final Determinations	
				Interval	Amount, Liters
1	4.4	1.2	1.6	8 mo.	3.9
4	4.5	0.4	1.5	2 mo.	3.3
5	4.4	1.3	2.0	4 mo.	3.6

pain with each attempt at coughing. He was gravely ill, and the temperature, which had previously been normal, rose to 101 F. Multiple injections of 3 to 4 cc. of a solution of 0.5 per cent procaine hydrochloride and 0.1 per cent eucupine dihydrochloride were made as nearly as possible into the site of each fracture (forty hours after the operation). The patient was relieved from pain immediately, and within fifteen minutes his cough became productive of plain and faintly blood-streaked sputum. The respiratory rate declined from 40 to 32.

From this point, the entire clinical picture shifted. The temperature declined to an average of 99 F. It was not again necessary to inject the solution into the fractured ribs, although moderate pain returned as the patient was able to expectorate collections of mucus from the upper respiratory tract. During the ensuing twenty-three days' stay in the hospital, the vital capacity slowly rose to 2 liters. Further increase was hampered by the collection of fluid in the right side of the lower part of the chest up to the sixth rib. Since the patient was not dyspneic except on moderate exertion, there was no indication for aspiration of the fluid. He continued to improve after leaving the hospital, but the vital capacity did not return fully to normal for two months, and the fluid did not all disappear from the right side of the chest until that time.

When last seen, eight months after the injury, he was working daily at moderately heavy manual labor without pain or dyspnea.

Roentgenograms showed the chest clear, and the vital capacity was 3.9 liters (table).

CASE 2.—Complete and permanent relief from pain in simple multiple fractures of ribs.

H. A. B., a woman aged 55, sustained contusions to the left shoulder and thoracic region from direct trauma in an automobile accident. When she was first seen rib strapping had been applied as an emergency measure elsewhere but had only partially relieved pain. Roentgenographic examination showed fractures of the eighth,

Fig. 4.—The chest in case 3. The arrows indicate the sites of fractures of ribs. Note the mottling over the left side of the upper part of the chest produced by subcutaneous emphysema.

ninth, tenth and eleventh ribs in the left anterior axillary line. When admitted, the patient was suffering severe pain in the left side of the chest and was unable to take a deep breath because of it. Severe pain was also present on movement of the left shoulder, but roentgenographic examination revealed no bony injuries there. Anesthesia of the painful areas in the

ribs was obtained by depositing 3 cc. of solution directly into each site of fracture. Relief was obtained immediately and persisted during the patient's remaining four days in the hospital. On discharge, the patient stated that the only pain she had had while in the hospital had been associated with movements of the shoulder or had been produced by sudden rising or twisting. Ordinary breathing efforts and motion had been entirely without pain.

CASE 3.—Fractures of ribs complicated by subcutaneous emphysema.

M. S., a frail woman aged 82, was involved in an automobile accident, suffering injuries to the left shoulder and the right side of the chest. She was admitted to the hospital on the morning after the accident. A local physician had strapped her chest, but this had not relieved the pain. She had not eaten the previous day because any movement of the neck, including deglutition, caused severe pain in the chest. She was likewise unable to turn herself in bed for this reason.

Roentgen examination revealed fracture of the second and third ribs near the left sternocostal margin and fracture of the right pubic ramus (fig. 4). There was considerable subcutaneous emphysema over the left side of the chest, which spread out over the left side of the neck and the left axilla. The patient was given a single injection of 10 cc. of a solution of procaine hydrochloride and eucupine dihydrochloride, this quantity being equally divided between the sites of fracture on the second and third ribs. From this time, the patient was able to sit in a semireclining position in comfort and to turn slightly in bed in accordance with preventive measures taken to prevent passive congestion, and she could take fluids and food orally without discomfort. The relief was instantaneous after injection and continued until the following day, when only slight discomfort in the chest returned. During the remainder of her hospital stay she was comfortable. The air beneath the skin was gradually absorbed, so that none was present ten days after injury.

CASE 4.—Fracture of four ribs in the left midaxillary line, with incomplete fracture of two of the ventral ends of the same ribs; hemothorax and subcutaneous emphysema.

G. M., a man aged 58, was struck by an automobile while walking on a highway and was brought immediately to the hospital. He had pain in the chest and expectorated a fair amount of bloody sputum. There was extensive subcutaneous emphysema over the left thoracic wall, the left side of the chest was hyperresonant and there were no breath sounds. Roentgenograms showed fractures of the fifth, sixth, seventh and eighth ribs in the left midaxillary line (fig. 5), incomplete fracture of the vertebral ends of the sixth and seventh ribs and an undisplaced fracture through the left pubis. A complete pneumothorax was visualized on the left. The vital capacity was but 0.4 liter (normal, 4.5 liters), but the test was unsatisfactory because of the extreme pain. He received an injection of 10 cc. of procaine hydrochloride-eucupine dihydrochloride solution into the site of fracture in the left midaxillary line and an additional 5 cc. into two contused areas in the right side of the chest, with immediate and permanent relief from pain. The patient volunteered that during the next week he was uncomfortable only on quick turning in bed. He was kept

Fig. 5.—The chest in case 4. The arrows indicate the fractures of ribs in the left midaxillary line.

in bed for ten days because of the complete pneumothorax. Periodic roentgen examination of the chest demonstrated fluid up to the tenth rib posteriorly and partial expansion of the left lung in ten days. When the patient was last seen, ten weeks after injury, the vital capacity, which for the first ten days after injury had remained between 1.4 and 2.3 liters, had risen to 3.3 liters. All symptoms had subsided.

CASE 5.—*Sternomanubrial dislocation.*

M. C., an obese man aged 46, injured the chest by direct impact of the body of the sternum against the steering wheel of an automobile. This resulted in tearing of the sternal manubrial ligaments, with anterior dislocation of the manubrium on the body of the sternum. Fracture of the right fourth, fifth, sixth and seventh ribs in the anterior axillary line also occurred (figs. 6 and 7). He was admitted to the hospital on the morning following the accident.

Physical examination at that time failed to reveal evidence of any trauma except that of the thoracic area. The patient was suffering considerable pain, and respirations were shallow and difficult because of it. He was immediately given an injection of 15 cc. of a solution of procaine hydrochloride and eucupine dihydrochloride into the site of dislocation. Five cc. of the solution was deposited with a long needle about the site of each fracture. The respiratory rate slowed from 40 to 28, the breathing became correspondingly deeper and the patient was immediately relieved from pain. The relief continued from noon until 10 p. m., at which time the patient complained of a return of discomfort, mainly at the site of dislocation in the anterior midline of the chest. He was given another injection of 20 cc. of a solution of procaine hydrochloride and eucupine dihydrochloride and passed a fairly comfortable night. From this point, thirty-six hours after the accident, the patient was fairly comfortable and required no injections.

During the remainder of his hospital stay, ten days, he suffered slight discomfort at the site of dislocation but in the main was free from the exquisite pain from which he had suffered on entrance. He was advised to spend several weeks in recumbency and extension because of the tendency for the superior fragment to be displaced. This advice was unheeded, and he insisted on leaving the hospital. Pain had not been a prominent feature of his course from the second day in the

hospital. He began to experience increasing pain in the back at the fourth and fifth thoracic segments and returned to the hospital for open reduction and fixation of the dislocation two months after the original injury.

COMMENT

The cases reported in this paper demonstrate the immediate and effective relief from pain obtained after minor fractures of the ribs (in 32 cases) and after major injuries to the chest (in 5 instances) through infiltration of a solution giving prolonged local anes-

thetic before the reduction of fractures of the long bones. This method eliminates rib strapping and sedatives, both of which exert unfavorable effects on thoracic injuries. Strapping the chest reduces the effective excursion of the chest wall and thus reduces tidal air and vital capacity and lessens the effectiveness of the cough reflex. Sedatives, especially drugs of the opiate series, depress respirations, decreasing pulmonary ventilation, and diminish the sensitivity of the cough reflex. Smaller doses of these drugs, which will not have the untoward effect mentioned, usually are not effective in controlling pain.

A more logical means of controlling pain is to interrupt the painful afferent stimuli at their origin at the site of fracture. To do this is compatible with the known effectiveness of local anesthetic agents in the treatment of sprains and other areas subjected to trauma. While fractures of the ribs and major injuries of the chest wall can be treated either by local infiltration of the anesthetic agent or by the production of regional anesthesia by paravertebral block, the latter is technically more difficult, and the end results are the same.

The comfort of all the patients on whom the method was used improved after the injection. Indeed, the method was considered life saving in 1 instance (case 1), since the entire clinical picture shifted after the use of the solution.

All authorities are agreed that injuries to the thoracic wall, including penetrating wounds, are best managed conservatively. Boland⁹ and Elkin¹⁰ reported a mortality of only 8.5 per cent from all types of pulmonary and pleural injuries in 1,009 cases in which such injuries presented most, if not all, of the clinical picture. The indications for operation for such injuries are usually extensive laceration of the pleural wall, with or without hemorrhage, and hemorrhage from the tearing of an intercostal artery. The occurrence of tension pneumothorax calls for careful aspiration of blood and air from the pleural space. Aspiration as a rule should be delayed twenty-four or forty-eight hours if possible, since a pleural tamponade will succeed in controlling hemorrhage in a certain number of cases. A review of methods and indications for treatment may be found in the article by Berry¹¹ and in the textbook of Graham, Singer and Ballou.¹²

thesia. When the precautions usually taken before the injection of a local anesthetic are observed, there is as much reason for the injection of this solution directly into the site of fracture in ribs as there is for the use of a

SUMMARY AND CONCLUSIONS

The use of a local anesthetic with a prolonged action in 32 cases of minor fractures of ribs and 5 major thoracic injuries eliminated the necessity of strapping the chest wall with adhesive tape and the excessive use of sedatives to control pain. A more physiologic state was thus preserved throughout convalescence. It is our clinical impression that the comfort of the patient is greater with this type of treatment than with any other.

LEPTOSPIRAL INFECTION (WEIL'S DISEASE) AS AN OCCUPATIONAL HAZARD

W. W. STILES, M.D.

AND

W. A. SAWYER, M.D.

ROCHESTER, N. Y.

Human leptospiral infections have been frequently associated with circumstances or occupations in which the patient has had contact with the excreta of rats or, rarely, with those of dogs. Isolated cases have been adjudged industrial accidents, and compensation has been awarded in this country and abroad. Recent investigations have shown an unsuspected incidence of the infection in certain occupations. This finding has increased the concern about the industrial liability that may be involved.

Leptospiral infections have been confused clinically with catarrhal jaundice and other diseases that have no occupational association. It becomes essential, therefore, to establish the diagnosis by laboratory methods. In this country at the present time a leptospiral infection is but rarely considered in the differential diagnosis until the disease has reached a critical phase, and even then laboratory facilities are so unavailable and methods so unfamiliar that a conclusive diagnosis is usually remote. It may be concluded that a leptospiral infection should be considered in the differential diagnosis of any illness of a patient whose occupation or circumstances bring him into contact with rat or dog excreta and that laboratory facilities and methods should be refined to insure a correct diagnosis. It is also important that workers and their employers should be informed of the potential hazard of material contaminated by rat and dog excreta and that precautions should be taken to prevent such contamination.

EPIDEMIOLOGY

Incidence.—Leptospiral infections have been recognized more extensively and with increasing frequency since the etiologic agent was first demonstrated by Inada and his colleagues in 1914. For example, in the Netherlands between 1924 and 1938 there were 852 reported cases.² Among those of known source, 257 cases (78 per cent) followed swimming or water accidents and 68 (22 per cent) were of occupational origin. Of the 68 patients 16 were fishermen, half of the 52 others were engaged in work that had to be performed on or in water (divers, seamen, reed cutters

and so on) and the other half were occupied in places overrun with rats (sewers, slaughter houses, butter factories, barns and stables). Thus, in 91 per cent of the cases infection followed contact with water contaminated with rat urine, and in the other 9 per cent there was contact with moist materials similarly contaminated.

In Great Britain between 1933 and 1939 there were 246 authentic cases of leptospiral infection.³ Of these, 144 (58.5 per cent) were in fish workers, 34 (13.8 per cent) in coal miners, 21 (8.5 per cent) in sewer workers, 16 (6.5 per cent) in swimmers, and the remainder were associated with at least seventeen occupations or circumstances. During a single year beginning in October 1933, 138 cases among sugar cane workers in Australia were reported.⁴ Of the 1,232 specimens of blood from persons suspected of suffering from leptospiral infection examined at the Pasteur Institute in Paris during 1933, positive agglutination tests were obtained in 23.1 per cent of the cases.⁵

Seventy-three cases of leptospiral infection in North America that seem authentic are tabulated in the present report. In addition, about half that number were reported as leptospiral infections by the respective authors, but in these the laboratory proof is not regarded as adequate. Several outbreaks of infectious jaundice in which leptospira organisms were implicated only by circumstantial evidence are omitted from our series.

The first case of authentic leptospiral infection was that of Stimson.⁶ He described an organism in silver-stained sections of the kidney of a patient who died in 1905 during a yellow fever epidemic in New Orleans. It was not until recently, however, that this organism, which Stimson called ? *Spirochaeta interrogans*, was recognized to be identical with *Leptospira icterohemorrhagiae*. Now it has been suggested that the term *Leptospira interrogans* deserves precedence.⁷ The second reported case occurred in Albany, N. Y., in 1921. This was a laboratory infection that was recognized immediately.⁸

The authentic cases of leptospiral infection in North America are arranged in tables 1, 2 and 3 according to the year, season and locality in which they occurred.

Leptospiral infections are more severe in older patients and far more common in males than in females. These facts are illustrated in a comparison of the Amer-

ican series with that of the Netherlands,² as shown in table 4. In the American series the mortality is 17 per cent in patients less than 40 years of age, 63 per cent in patients more than 40 years of age and 33 per cent in the entire group. In the Netherlands series the mortality is 7 per cent, 33 per cent and 12 per cent, respectively, for these groups. The higher mortality in the American series is explained in part by the fact that mild forms of leptospiral infection are often overlooked in this country.

The circumstances or occupations involved in the American series are shown in table 5.

Mode of Infection.—Leptospiral infection is considered to be possible through the intact skin and mucous membranes as well as through these tissues after injury. Usually it follows contact of the abraded or sodden skin with infected mud or water, but it may follow the inhalation of water or the bites of rats, dogs or ferrets.¹ One patient who was found to have a latent leptospiral infection said that he had been bitten by rats on several occasions during the eighteen years that he had lived on a city dump. Four other persons who were severely bitten by rats gave no evidence of a leptospiral infection. White rats may become carriers of leptospira organisms and have been responsible for human infections.⁹ One instance has been mentioned in which infection resulted from stepping with an abraded foot on the blood of a rat that had just been killed.¹⁰ Mechanical transmission of the infection has occurred, as illustrated by a case resulting from the bite of a dog that had previously killed a rat and by two other cases following the bites of ferrets that had had contact with rats.¹¹ In another instance the macerated tissue of a rat that had been caught in a dairy machine was spattered in the face of the patient. Occasionally, association of human cases with infected dogs has been reported.¹² Contact with a jaundiced pig has been mentioned.¹³ One case attributed to coitus has been recorded¹⁴ and another considered to be probable in the American series. It has been suspected that contact with postmortem tissues has been responsible for several cases.¹⁵ A number of laboratory infections have been known;¹⁶ among them two are included in the American series.

The vast majority of human leptospiral infections have originated from water or moist objects contaminated with infected urine. In most countries it has been shown that the kidneys of about 20 per cent of the wild rats are infected with leptospira organisms.² Infected dogs also have been recognized as chronic shedders of pathogenic leptospira organisms.¹⁷ White rats,⁹

gophers,¹⁸ foxes,¹⁹ ferrets,²⁰ guinea pigs²¹ and other animals have been infected experimentally or found to be diseased naturally. They must therefore be considered as potential vectors. The urine of infected human beings has also been regarded as hazardous in the spread of the disease.²²

Vivulent leptospira organisms have been found to be viable for at least twenty-two days in surface waters,²³ and they have been maintained in artificial mediums for five hundred and eighty-five days.²⁴ Leptospira organisms of debatable pathogenicity for man have been found widely distributed in water, slime and mud.²⁵ Water-borne epidemics have been usually associated with submersion in the water, although one unproved drinking water epidemic has often been quoted.²⁶ Acid soils and water (p_H less than 6.8) have rarely been found to contain leptospira organisms;²² likewise leptospira organisms have rarely been found in soil or water having a concentration of salt above 0.17 per cent.¹ That the organism quickly dies in an acid medium, in

salt water and in strong sunlight is in accord with the known distribution of the human disease.¹

Compensation Awards.—In Germany during 1922 or thereabouts a man developed a fatal leptospiral infection two weeks after falling into a cesspool. This case was analogous to one already published by Stirl. In both instances the right to workman's compensation was recognized.²⁷ Another case was reported in 1927, that of a man who fell into a ditch, swallowed some of the

men who worked in the drains, a dock laborer working on a dredger in the harbor and 2 other cases among the crew of a ship overrun with rats may be cited.²⁹ In the fatal case of the Hamburg dock laborer it was necessary to pay compensation.

A legal precedent was established in England in 1925, when compensation was awarded for the death of a coal worker who had a leptospiral infection.³⁰ The award was contested in the Court of Sessions but dismissed. The case in question was *Racburn v. Lochgelly Iron and Coal Company, Ltd.* (20 B. W. C. C., 637).

In England the Departmental Committee on Compensation for Industrial Diseases in its third report, 1935, came to the following conclusions:

After reviewing the evidence the Committee recommends that infection by *S. icterohemorrhagiae* should entitle a workman to compensation for disablement, but only if confirmed by bacteriological or serological examination. In fatal cases, pathological evidence of the infection should be accepted. In the event of the disease becoming more widespread or of other developments, it may be found that it ought no longer be scheduled as an industrial disease.³¹

The committee found that a recent and acute infection can be diagnosed either serologically by a high or ascending titer or bacteriologically by demonstrating the leptospira in the blood or urine, directly or by animal inoculation. It is difficult to prove that death is caused by the disease, because the changes found after death are not specific; moreover, a patient may die in the second week, before material for laboratory examination has been obtained. Nevertheless, the committee is satisfied that it is reasonably certain that death was caused by the disease if the claimant can show morbid changes compatible with it,

an appropriate history and clinical picture, and the absence of any other recognizable cause of death. Under the Act, the certifying surgeon must examine the workman personally, but the committee considers that it should rest with the workman or some one acting for him to produce the laboratory evidence in support of his application.³²

In England, in an arbitration heard by Judge Dumas at the Westminster County Court on May 17, 1935,³³ £600 compensation was awarded the widow and three young children of a sewer worker who died of a leptospiral infection. On June 29, 1936 an award of £435 6s. was paid the widow of another sewer worker who died of the infection. Testimony presented at the Clerkenwell County Court revealed that the plaintiff abraded his knuckles while using a chisel in the sewer during the early part of August 1935. For a few days nothing was thought of the injury but he became ill, stopped work during the latter part of the month and died on September 11. *Leptospira* organisms were isolated from the patient's blood by the inoculation of a guinea pig. It was brought out by the attorney for the plaintiff that both the injury and the infection occurred while the patient was working but that compensation was entitled whether the injury occurred at work and the infection elsewhere or the injury elsewhere and the infection at work. As to notice of injury being reported to the company, which was a crucial question in the case, it was ruled that it was given "as soon as practicable after the accident," even though it was not reported officially until death (*Stiles v. John Nowlem and Co.*).³⁴ About the same time a miner's wife, the mother of four children, was awarded £600 compensation by the Newcastle County Court. Her husband had contracted a leptospiral infection while working underground in water. The company was not satisfied with

In Australia, leptospiral infections were also made a compensable disease under the worker's compensation act. In 1936, 57 patients had received compensation, as shown in table 6.

In the United States the first case of leptospiral infection in which compensation was awarded was that of Glotzer.³⁶ The patient was a man aged 33 who was

engaged by a wholesale merchant in New York City to fillet fish. He became ill while at work on Oct. 2, 1937. His illness was that of a severe hemorrhagic jaundice, and the diagnosis of a leptospiral infection was established by serologic tests performed at the National Institute of Health. The case was first disallowed, when considered by the New York State Workman's Compensation Division. Following an appeal, however, an award for ten weeks of disability was made on June 2, 1938. Later, consideration was given to the possible causal relationship between the leptospiral infection and more recent symptoms suggesting a chronic cholecystitis, but to date no decision has been made.

Compensation was awarded in a second nonfatal case of leptospiral infection in a fish worker in New York on March 10, 1939.³⁷ The patient was a man aged 36 who became ill on Aug. 7, 1938. A blood specimen taken on the fifteenth day of illness was found to contain a high titer of leptospiral agglutinins.

In a third case of leptospiral infection compensation was also awarded in New York State.³⁸ A man aged 41, a street and sewer cleaner in Newark, fell from a truck on Sept. 22, 1938, injuring his right side. He was hospitalized for eight days because damage to the right kidney was suspected, but his clinical course was uneventful. Thereafter he convalesced in his two room shanty on the bank of the Erie Barge Canal until October 28. At that time he became acutely ill, suffered a hemorrhagic jaundice and died on November 10. The diagnosis of a leptospiral infection was confirmed by the examination of silver-stained sections of the lungs and kidneys. It was held that there was a causal relationship between the injury and the fatal infection. Subsequent independent investigations, however, point to an error in this connection, for thirty-six days elapsed between the accident and the onset of the fatal illness—a period greater than the recognized incubation period of leptospiral infections.

Realizing the potential hazards in certain occupations, employers have already undertaken preventive measures.³⁹ Attempts have been made to reduce the contamination of water and other materials by exterminating rats, eliminating refuse and rat proofing build-

ings. To destroy the leptospira organisms in nature, drainage of stagnant water and disinfection have been tried. An effort has been made to protect workers by the use of suitable clothing and by active immunization.

COMMENT

Leptospiral infection may be considered as an occupational hazard, provided the occupation exposes the patient to rats or dogs, or to moist materials contaminated by the urine of these animals, and provided that the illness follows such exposure by the recognized incubation period of from two to nineteen days. Certain other criteria should be fulfilled before a leptospiral infection is considered as compensable. A nonoccupational source of infection should be eliminated as a probability. If the patient has been swimming or wading in water that may have been contaminated by rats or dogs, it is more likely that this was the source of his infection. If the patient has had contact with a pet dog, the animal should be studied for evidence of a leptospiral infection. If the dog is proved to be a shedder of leptospira organisms that are pathogenic for guinea pigs, it is probable that infection arose from this source. A rat-infested residence must also be eliminated as a probable source of the infection. It is imperative to prove that the patient is suffering from a leptospiral infection and not from some other illness that may be easily confused with the leptospiral disease.

Of the laboratory methods available for the positive diagnosis of leptospiral infections, the most conclusive is the reproduction of the disease in guinea pigs that have been injected with macerated tissue or fluids from the patient, and recovery of leptospira organisms from these animals. Properly controlled serologic tests are reliable when the titer is found to be high or rising. An instance has been encountered in which a low agglutinin titer persisted throughout an illness that was confused clinically with a leptospiral infection but that was finally considered to be of other causation.⁴⁰ Histologic sections of the patient's tissues stained by silver technics are acceptable evidence, provided organisms that have the characteristic morphology and staining characteristics of leptospira organisms are found.

Unreliable laboratory technics include those in which darkfield microscopy is used. Confusing artefacts are common in body tissue and fluids, as pointed out repeatedly in the medical literature.⁴¹ In spite of this knowledge, many cases have been reported in the United States in which the diagnosis of a leptospiral infection was based solely on the finding of "organisms resembling leptospira" by darkfield microscopy. Pseudo-spirochetes have been observed in tissues and fluids of persons in good health and in those of patients suffering from other diseases. Many specimens "swarming" with these artefacts have been injected into susceptible guinea pigs without producing leptospiral infection. Other specimens exhibiting no leptospiral forms by darkfield microscopy have proved to be

39. Bonning,²³ Glotzer,³⁶ Taylor and Goyle.²²

infectious for guinea pigs. Several American authors recently interviewed have expressed the opinion that they have confidence in their own darkfield technics yet are skeptical of the results of others. Others have admitted that they could not rely on their own darkfield observations and that they would not accept those of others.

Several cases have been studied carefully in which the clinical history or postmortem findings were compatible with a leptospiral infection, and yet no positive evidence of an infection, as ascertained by multiple animal injections, serologic tests or the study of histologic sections has been found. A diagnosis of leptospiral infection that is based solely on the clinical history, darkfield microscopy or gross postmortem findings is therefore unreliable.

SUMMARY

Certain occupations expose workers to a risk of leptospiral infection that is greater than the risk run in private life. Compensation for an industrial infection is therefore justified, provided nonoccupational circumstances can be ruled out as more likely sources of the infection and that the leptospiral etiology can be established conclusively.

Leptospiral infection should be considered as an occupational hazard—not as an occupational disease.

SPECIAL NOTE—Since the present paper was accepted for publication, we have learned of more than a score of additional cases, details of which will be reported in a forthcoming paper on the incidence of leptospiral infections in the United States

THE TREATMENT OF PEPTIC ULCER WITHOUT ALKALIS

GEORGE F. DICK, M.D.

AND

C. WESLEY EISELE, M.D.

CHICAGO

The use of alkaline substances in the management of peptic ulcer is almost universal, and such treatment is recommended in nearly all the current textbooks dealing with the subject.¹ It is commonly assumed that complete neutralization of gastric acidity represents the ideal condition for ulcer healing, although no proof of this assumption exists. Furthermore, it is not certain that the highly alkaline stomach content obtained periodically in the course of alkali therapy is conducive to healing. That the conventional methods of treatment are not entirely satisfactory is manifest by the fact that scarcely a year passes without one or more new "ulcer treatments" being advocated. At frequent intervals new kinds of neutralizing agents, supposedly with better virtues or fewer evils, are recommended.

The disadvantages of alkali therapy, which have been commonly recognized during its wide use, are:

1. Alkalis may produce secondary acid secretion. Crohn and Reiss² state that alkalis are second only to

histamine in their power to stimulate acid secretion. Wosika and Emery³ estimate that in the Sippy treatment fifty times as much alkali is given as would be required to neutralize all the acid normally secreted by the stomach, but even so the acidity is not entirely controlled. Two explanations are offered for this fact. The alkali may stimulate gastric secretion or it may induce more rapid emptying of the stomach. They express the belief that both factors are involved.

2. On occasion, alkalosis may be produced. This is particularly true of patients with pyloric obstruction, renal impairment or severe anemia. Eisele⁴ has shown that all patients following the Sippy treatment suffer from some degree of chemical alkalosis, with an elevation of both the p_H and the carbon dioxide content of the plasma above normal. Although the patients who suffer from a full blown clinical alkalosis are relatively few, instances are numerous in which minor symptoms require the withdrawal of alkalis for a few days.

3. Some of the alkalis, notably calcium carbonate and phosphates and bismuth compounds, cause constipation. In most cases it is necessary to add magnesia as a cathartic, and in some cases an undesirable cathartic colitis develops.

4. As has been shown by Eisele,⁵ the use of alkalis may result in the formation of kidney stones.

5. The use of aluminum hydroxide and aluminum sulfate, which recently has become quite widespread, may have deleterious effects. Therapeutic doses may interfere with the absorption of inorganic phosphates from the intestinal tract, thereby deranging the calcium metabolism of the body.⁶ Constipation and fecal impaction may occur,⁷ and even intestinal obstruction has been reported.⁸

For many years one of us (G. F. D.) has treated peptic ulcers essentially without the use of alkalis; that is, they were given only in individual doses when necessary to control pain early in the course of treatment. It is our purpose in this report to show not only that many patients recover from peptic ulcer without alkali therapy but also that it is doubtful whether the use of alkalis ever results in more rapid recovery. This idea is not new. Brinton⁹ in 1862 said that many patients get well with diet alone, but this seems to have been largely forgotten.

EVALUATION OF EVIDENCE OF HEALING

The difficulty of evaluating any regimen of ulcer treatment is well recognized. Under a wide variety of treatments, or with no treatment at all, ulcer pain may disappear and the patient may be completely comfortable within a few days, yet roentgenologic and pathologic evidence may show an unhealed ulcer still present.

Gaither,⁹ quoting Hurst and Eusterman, has reported numerous instances in which ulcers were "cured" by parenteral treatment, the patient being entirely symptom free but an ulcer as large as ever being found at operation.

The disappearance of occult blood from the stool is taken as an objective sign of healing, but this too is not

METHODS AND MATERIAL

In the present study 41 patients with peptic ulcers were selected on the basis that their x-ray studies before treatment showed definite ulcer craters and that subsequent studies were made at sufficiently frequent intervals to indicate the course of the crater. As this was the only criterion for selection, this group should not show a more favorable response to treatment than the series as a whole. Actually, this selection probably affected the group adversely, for it included more than its share of severe cases requiring prolonged periods of hospitalization and but few completely ambulatory patients. This was true because the patients with long hospitalization afforded better opportunities for the repetition of x-ray studies at sufficiently short intervals. Six of the patients had suffered recent gross hemorrhages.

These patients were given 1 to 4 ounces (30 to 120 cc.) of a mixture of equal parts of milk and cream at hourly intervals during the day and often during the early evening. In a few instances in which cream was poorly tolerated, milk alone was given. When all distress was relieved, small amounts of bland foods were added gradually. Added vitamins were given in most cases. The importance of physical and mental rest was emphasized. Atropine was given in some cases. In 8 cases a few single doses of alkali were given to control pain. Attention was directed to the removal of foci of infection when such were present. Therapeutic aspiration of the stomach at bedtime, a com-

Fig 1 (case 41)—Ulcer crater of the lesser curvature of the stomach in profile view. The crater measures 24 mm. in diameter and 9 mm. in depth. After forty five days of treatment the crater had disappeared completely, leaving only a scar that was detected with difficulty.

wholly reliable. The disappearance of the gastric ulcer niche as detected by x-ray studies has for many years been accepted as the most satisfactory evidence of healing.¹⁰ But, until Berg's controlled compression technic was introduced into this country in recent years, similar observations were not feasible for duodenal ulcers. Berg reported finding craters in 50 per cent of his cases of duodenal ulcer, but prior to the use of this technic craters in duodenal ulcers were seen in only the occasional case. Templeton, Marcovich and Heinz¹¹ state that "the best clinical evidence of activity and healing is the roentgenologic demonstration and the progressive and complete disappearance of the crater. Our observations confirm those of others that a large percentage of niches persist for a considerable time after symptoms are clinically relieved." These authors as well as others¹² warn that the disappearance of the crater is not necessarily synonymous with complete healing. The crater may be filled with granulation tissue but not yet epithelized. On occasion the crater may be filled with food, mucus or blood clot. Nevertheless, crater disappearance is the best clinical criterion of healing.

Fig 2 (case 5)—Duodenal ulcer crater 23 mm in diameter (shown to be 15 mm deep in other views). After forty-eight days of treatment the crater had disappeared but definite bulb deformity remained. Subsequent x-ray studies confirmed the disappearance of the crater.

mon custom under many regimens, was not done. Instead, one or more bedtime aspirations were done when treatment was begun, and in cases showing residuum the quantity of milk and cream per hour was reduced until the stomach was practically empty at bedtime. We believe that the results so obtained are better

than giving an arbitrary amount of feedings and then aspirating the retained food every night. We further made an attempt to adjust the volume of the hourly feedings so as to induce the complete comfort of the patient.

Seven patients were suffering from gastric ulcers¹³ and 34 from duodenal ulcers. Two of the latter group were followed through two distinct attacks, thus making 36 duodenal ulcers in the series. Twenty-six of the patients were men and 15 were women. The ages ranged from 23 to 74 years, the average age being 40 years. Five were entirely ambulatory and 36 were hospitalized for periods varying from three to fifty-two days, the average being twenty-four days.

RESULTS

The time of disappearance of the x-ray crater in each case is represented by a bar in the accompanying chart. The left end of the bar indicates the time (days of treatment) of the last x-ray examination at which a crater was demonstrated, and the right end the time of the first examination at which the crater had disappeared. In 25 cases the last demonstration of the crater was at the initial examination. It will be noted that in 17 cases an average of seventy-six days (ranging from fifty-two to one hundred forty days) elapsed between these two pertinent examinations. Unfortunately, this introduced a considerable latitude as to the actual time

The table summarizes the time of the disappearance of the craters in the cases of duodenal ulcer. It will be noted that 86 per cent had disappeared within seventy-five days (mean time of crater disappearance) and that in 70 per cent of the cases the crater was actually demonstrated to have disappeared within seventy-five days. In 2 cases (6 per cent) the craters did not dis-

Disappearance of X-Ray Crater in Duodenal Ulcers

Days of Treatment	Examination When Crater Had First Disappeared		Mean Time of Crater Disappearance	
	No. of Cases (Cumulative)	Per Cent	No. of Cases (Cumulative)	Per Cent
Within 15 days	3	5	8	22
Within 30 days	10	28	18	50
Within 45 days	13	36	27	75
Within 60 days	21	58	30	83
Within 75 days	25	70	31	86
More than 75 days	34	94	34	94
Nonhealing	2	6	2	6

appear completely although they decreased in size considerably. One of the patients was symptomatically well and apparently in good health after the first week of treatment. In the second case a duodenal ulcer crater disappeared promptly without the use of alkalis one year before, but in the attack under consideration the crater persisted for seventy-five days, although it became shallow with indistinct margins, thus showing definite evidence of healing. Subsequently the crater disappeared with the administration of alkalis.

The cases of gastric ulcer were too few for adequate analysis, but in general they followed a similar course. Again, in 2 instances healing did not take place. In 1, surgical treatment was necessary after one hundred and ten days. The other patient left the hospital against advice after three days of treatment and he followed management very poorly. His ulcer distress had been present for over twenty years.

No definite correlation was found between the age of the patient and the time of crater disappearance or between the duration of ulcer history and crater disappearance.

As others have noted, complete relief of symptoms occurred in nearly all cases long before the crater disappeared. In 31 cases all symptoms were controlled within one week. In 9 cases the progress notes concerning relief from pain were inadequate. In the case in which the duodenal ulcer did not disappear during the second attack, symptoms persisted irregularly for many weeks.

The benzidine reaction of the stools was negative in 14 cases despite the presence of a crater. In 12 cases a positive test became negative before the x-ray examination which first showed the disappearance of the crater. In 1 case a positive benzidine test persisted after the crater disappeared.

COMMENT

These data demonstrate that healing of peptic ulcers will progress satisfactorily without the attempted neutralization of gastric acidity with alkalis. It appears that it is only in the exceptional case that recovery will take place on alkali therapy and not without it. On the other hand, we have observed several patients who

Fig. 3.—Time of x-ray crater disappearance. Each case is represented by a bar, the left end of which indicates the time of the last x-ray examination at which a crater was demonstrated; the right end indicates the first examination at which the crater had disappeared. The midpoint of each bar, indicated by a dot, represents the most probable time of crater disappearance. A circle at the right end of a bar indicates that the crater was still present at the last examination.

of crater disappearance. The midpoint of each bar, indicated by a dot, represents the most probable time of disappearance (the mean time of crater disappearance).

13. In 1 case, two craters were followed to healing gastroscopically instead of roentgenologically.

did poorly on Sippy treatment whose response was notably better with the management described in this paper.

The speed of recovery compares favorably with that under any other type of treatment. We were unable to find in the literature a series of duodenal ulcers treated by the Sippy regimen and adequately observed by x-ray studies of crater behavior. However, the results in our series of duodenal ulcer compare very favorably with those obtained by Jordan and Boynton¹⁴ in their series of 41 cases of gastric ulcer treated by Sippy management—although several authors¹⁵ have stated the belief that gastric ulcers heal more rapidly than duodenal ulcers. In their series of 41 patients with ulcers of the lesser curvature, 9 were operated on because of inadequate diminution of crater or persistence of symptoms, 13 healed, with crater disappearance, within twenty-one to twenty-eight days of hospitalization, and 19 healed within four to ten weeks after leaving the hospital.

Our results with milk and cream without alkalis are not surprising in view of the observations of Wosika and Emery.³ They performed half hour titrations of free and total acid of the gastric contents of ulcer patients receiving hourly feedings of milk and cream, and subsequently of the same patients receiving the first day Sippy treatment (hourly milk and cream plus hourly powders on the half hour). On the Sippy treatment the free acid was depressed an average of only 2 clinical units in comparison with the titrations with milk and cream alone. The patients were then divided into four groups according to the effectiveness of acid control, and no appreciable advantage of the first day Sippy treatment over the treatment with milk and cream was noted.

The treatment of peptic ulcer is usually considered to consist of two phases, the treatment of the immediate attack and the prevention of recurrences. Peptic ulcer is notoriously a chronic disease subject to recurrences, perhaps spontaneously, perhaps under adverse conditions such as fatigue, emotional stress and infections. It is not within the scope of this paper to discuss the prevention of recurrences. It is illogical, however, to expect the use of alkalis to prevent recurrences unless one is willing to advise such use throughout the life of the patient.

In many instances such ingestion of alkali would probably be more detrimental than the ulcer itself. Except for general hygienic measures, adequate prevention of recurrences awaits the solution of the problem of the etiology of ulcer.

SUMMARY

Under hourly treatment with milk and cream without the use of alkalis, the speed of healing of gastric and duodenal ulcers compares favorably with that under other methods of treatment. Such treatment of a series of 41 patients brought about (1) the prompt disappearance of symptoms and the complete comfort of the patient, (2) the disappearance of occult blood from the stool when it was present and (3) the disappearance of the x-ray crater.

Clinical Notes, Suggestions and New Instruments

ALOPECIA FROM CYVERINE HYDROCHLORIDE

OSCAR L. LEVIN, M.D., AND HOWARD T. BEHRMAN, M.D.
NEW YORK

Our purpose in this paper is to report the occurrence of alopecia following the use of a new antispasmodic drug. In this case, the defluvium followed the daily ingestion, for thirty days, of cyverine hydrochloride (Stearns) and rapidly progressed to involve the entire scalp.

REPORT OF CASE

History.—A white woman aged 49 was seen in consultation on June 6, 1941, complaining of an extreme degree of falling out of the hair of ten days' duration. She gave a history of spasmodic pain in the lower part of the abdomen for the previous three months, for which she had been under the care of her family physician. During this period, several examinations including roentgen ray and proctologic studies

Fig 1—Appearance of scalp on June 23, showing loss of hair from the temporo occipital region.

of the intestinal tract disclosed no abnormalities, and the diagnosis of a functional intestinal disorder was made. On April 24 the patient was instructed to take cyverine hydrochloride (Stearns), an antispasmodic, for the relief of her symptoms.

She took 40 mg. daily for three days and then 80 mg daily for four days. At that time, she complained of a sensation of numbness of the arms. She continued to take the pills until May 9, after which she stopped taking the medication because she had finished her prescribed supply (800 mg.). On May 18 she again took 40 mg. daily, but within three days the patient noticed that ordinary combing of the hair resulted in the accumulation of hundreds of hairs on the comb. This defluvium increased so rapidly that within ten days the occipital region of the scalp was almost entirely devoid of hair. At the same time the patient noticed that her skin was extremely dry and was covered with fine, branny scales. She also observed that her eyebrows and eyelashes were turning white.

The patient also gave a history of having had her hair dyed several times during the past three years. The last application of dye was made two weeks prior to the occurrence of alopecia.

substantiated in some measure by the finding of arsenic and lead in the body fluids and tissues in a series of these cases.⁵ The presence of these heavy metals in the body was accounted for by the widespread prevalence of arsenic and lead in foods, drugs and liquids due to contamination and spray residue. Chronic arsenical poisoning has long been recognized as a causal agent in alopecia and precancerous keratoses.

In this case, the drug which produced the alopecia is known as cyverine hydrochloride (Stearns). The chemical formula is methyl-bis-beta-cyclohexyl-ethyl-amine hydrochloride. It is a white crystalline powder, soluble in water up to 1 per cent and freely soluble in alcohol. It has a bitter taste, and on mucous membranes it has a mild local anesthetic effect. The empirical formula is $C_{17}H_{33}N.HCl$.

The structural formula of the cyverine base closely resembles that of papaverine. The structural formulas of cyverine and papaverine differ mainly by a break in the isoquinoline ring in cyverine, by which a prolongation in the chain is produced, each end of the chain carrying a cyclohexyl ring.

Fig 4—Appearance of scalp on July 14, showing almost total loss of hair.

Pharmacologic studies have shown that cyverine hydrochloride acts directly on smooth muscle tissue because it produced complete relaxation of smooth muscle sections (small intestine of rabbit) when the latter were (1) contracted by such parasympathetic stimulants as pilocarpine and arecaline, (2) contracted by a smooth muscle stimulant such as barium chloride, (3) atropinized and contracted by barium chloride and (4) nicotinized and contracted by barium chloride.

Clinical studies of 31 cases⁶ reported but not cited by the manufacturer showed that cyverine hydrochloride has a powerful antispasmodic effect. It is apparently of value in disorders such as pylorospasm and other spastic conditions affecting the gastrointestinal tract. In this series of cases no toxic symptoms were reported other than nausea, "heartburn" and slight dryness of the throat.

The suggestion is advanced that the effects of the drug on smooth muscle caused complete relaxation of the erector pili muscles around the hair follicles. In this manner loosening of the hair shaft and subsequent alopecia may have occurred.

6. Form 2625, a pamphlet entitled "Cyverine Hydrochloride," issued by Frederick Stearns & Co., Detroit.

SUMMARY

1. A white woman aged 49 years ingested 920 mg. of cyverine hydrochloride (Stearns), an antispasmodic drug, within a period of thirty days. At the end of this time alopecia of the scalp developed.

2. The alopecia was progressive and resulted in approximately complete loss of hair from the scalp.

Fig. 5—Another view of patient on July 14

Fig 6—Another view of patient on July 14

3. The eyebrows and eyelashes turned a grayish white shortly after the occurrence of alopecia.

4. There was an associated exfoliative dermatitis of the skin and a diminution in perspiration.

HYPERTENSION IN A PATIENT WITH BILATERAL
RENAL INFARCTION

CLINICAL CONFIRMATION OF EXPERIMENTS IN ANIMALS

MYRON PRINZMETAL, M.D.; NATHAN HIATT, M.D., AND L. J.
TRAGERMAN, M.D., LOS ANGELES

Goldblatt,¹ in a series of historic experiments, showed that hypertension was induced in animals by constricting the renal arteries. Numerous investigators have confirmed and amplified these observations on various animals, and it is now universally admitted that lasting hypertension follows the experimental induction of partial renal ischemia.

Goldblatt² later showed that hypertension also occurred following complete occlusion of one renal artery provided the renal vein was not obstructed.

Taquiní,³ modifying the Goldblatt procedure, showed that a temporary rise in blood pressure occurred in dogs on the reestablishment of the circulation in kidneys rendered completely ischemic for a period of from four to six hours. Taquiní's observations have been confirmed by us on cats, dogs, rats and guinea pigs,⁴ although negative results were obtained in

Fig. 1.—The effect of renal infarction on blood pressure, nonprotein nitrogen and urinary output. Note rise in blood pressure and nonprotein nitrogen; also decrease in the estimated urinary output.

rabbits.⁵ The mechanism responsible for the form of hypertension induced by the Taquiní method has been the subject of extensive investigation. It was found that an extract of a kidney made completely ischemic by clamping the renal pedicle for from four to six hours contained more pressor substance (renin) than that prepared from the opposite kidney

with the circulation unimpeded.⁶ Later it was shown that the same pressor substance or a similar one was present in perfusates of completely ischemic kidneys but absent from perfusates of normal kidneys as well as from perfusates of ischemic tissues other than kidney. It was conclusively proved that the pressor substance found in perfusates of completely ischemic kidneys is the cause of this type of hypertension,⁷ and there was strong evidence to show that this pressor material is renin or a closely related substance.

The sequence of events during complete renal ischemia and following the reestablishment of the renal circulation can be reconstructed as follows: As a result of complete renal ischemia more renin is formed in the kidney, or that which is present becomes more readily available for extraction. Normally the kidney secretes little or no renin, since perfusates of normal kidneys do not have pressor properties. When the kidney is deprived of its blood supply, pressor material passes from the depots of manufacture and storage through the vascular endothelial cells into the renal blood vessels. A small amount of the pressor substance reacts with some of the plasma in these vessels to form a minute amount of heat-stable pressor substance,⁸ but the bulk of transported material remains unaltered during the period of ischemia. When the renal blood supply is restored, the pressor substance enters the general circulation and a rise of blood pressure takes place, presumably through its transformation into a heat-stable substance termed angiotonin⁹ or hypertensin.¹⁰

In this communication we wish to report confirmation in a clinical case of some of the aforementioned observations on experimental animals. A patient suffering from chronic rheumatic heart disease was observed to become hypertensive following complete occlusion of both main renal arteries, the blood pressure having been followed from normal to hypertensive levels. Renal perfusates prepared immediately after death revealed the presence of appreciable quantities of a pressor substance presumably similar to that which causes the hypertension following complete renal ischemia in animals.

REPORT OF CASE

History.—A woman aged 53 was admitted to the Cedars of Lebanon Hospital on Sept. 1, 1940. On the previous evening severe epigastric pain suddenly developed and she became faint. Within the next few minutes she became nauseated and dyspneic. Because of the persistence of these symptoms she was admitted to the hospital. She was known to have had rheumatic heart disease of many years' standing. Her blood pressure taken on several occasions before the present episode was found to be normal.

Examination.—On admission to the hospital the radial pulse was 120 a minute, with evidence of auricular fibrillation. There was no cardiac enlargement and the blood pressure was 110 systolic and 95 diastolic.

Course.—The day after admission her blood pressure was 130 systolic and 100 diastolic and she was given quinidine, which converted the auricular fibrillation to normal rhythm. On the tenth day the blood pressure was 170 systolic and 110 diastolic and on the twelfth day 200 and 120. The urinary secretion, which had been diminishing progressively, almost ceased. On the eighteenth day, the blood pressure was 190 systolic and 100 diastolic and the specific gravity of the urine

had fallen to 1.008. Measurable quantities of albumin were present in the urine, and in the sediment there were numerous leukocytes, epithelial cells and a moderate number of erythrocytes but no casts. The nonprotein nitrogen rose to 72 mg. per hundred cubic centimeters on the seventh day after admission to 148 mg. on the day before death. There was increasing

Fig. 2.—Artist's drawing showing complete thrombotic occlusion of right renal artery (a) and extension of thrombus into left renal artery (b). Note multiple infarcts of kidney. A portion of thrombus lower down in the aorta is shown.

stupor, and death occurred on September 21, three weeks after admission (fig. 1).

A clinical diagnosis of occlusion of both renal arteries was made. The most probable cause was considered to be embolism, although the possibility of a dissecting aneurysm of the aorta involving the orifices of both renal arteries was also considered.

Postmortem Examination.—Autopsy was performed within one hour after death. The heart weighed 275 Gm. All chambers except the left ventricle were dilated and there were no mural thrombi. Moderate fibrosis with stenosis of the mitral valve was present, as well as slight thickening of the aortic valve. The aorta showed severe atheromatous disease with ulceration of the intima. An irregular friable gray-brown thrombus 3.5 cm. in length incompletely obstructed the aorta at the level of the renal arteries. The entire length of the major right renal artery and the first portion of the left renal artery were occupied by similar thrombotic material (fig. 2). A separate inferior renal artery on the right side was patent except where it was obstructed at its orifice by thrombus. The intima of the aorta and renal arteries underlying the thrombi showed atheromatous changes similar to those found elsewhere. Another more recent thrombus overlay the mouth of the inferior mesenteric artery and partially saddled the bifurcation of the aorta.

The left kidney weighed about 175 Gm. The capsule was adherent and thickened. Except for the lower pole, which

Fig. 3.—Effect of intravenous injection of perfusate from infarcted kidney on blood pressure of cat anesthetized with soluble pentobarbital. At the first arrow 2 cc. of perfusate was injected and at the second, third and fourth arrows the injections were 4 cc. Note diminishing pressor effect (tachyphylaxis). Time in minutes.

appeared fairly normal on gross examination the remainder of the kidney was mottled by numerous confluent zones of recent infarction.

The right kidney weighed 190 Gm. The renal artery was patent beyond the occlusion in its first portion and showed

only slight narrowing by intimal atherosclerotic change. The capsule was adherent and recent infarction involved almost the entire kidney, both cortex and medulla, except for an ill defined zone at the upper pole. A large tributary of the renal vein was obstructed by recent antemortem thrombus. The lower urinary tract was normal. The spleen weighed 200 Gm. and contained numerous infarcts.

Histologic Examination.—The renal arteries and aorta in the region of the major thrombus showed varying degrees of intimal atheromatous changes but no inflammatory lesions. The oldest portions of the thrombus were found in the medium size branches of the left renal artery within the kidney, where organization was well established. In the left renal artery the process appeared more recent than within the kidney but older than in the aorta and right renal artery. The renal parenchyma on both sides showed the typical changes of infarction. In the portions of both kidneys which were grossly spared, the histologic appearance varied from normal to intense hyperemia and tubular degeneration.

The anatomic diagnosis was chronic rheumatic disease of the mitral and aortic valves with mitral stenosis; occlusion by thrombus formation, probably embolic in origin, of the left renal artery with extension to the aorta and right renal artery; extensive bilateral renal infarction; multiple infarcts of the spleen; severe atherosclerosis of the aorta and coronary arteries, and thrombus near the bifurcation of the aorta.

DEMONSTRATION OF PRESSOR SUBSTANCE IN PERFUSATES OF PATIENT'S KIDNEY

Since the sequence of events in this case appeared to follow the pattern of experimentally induced hypertension, it was resolved to prove, if possible, whether the mechanism for the

Fig. 4.—Effect of experimentally prepared renal pressor substance on the blood pressure of a cat anesthetized with soluble pentobarbital. Note similarity to results shown in figure 3.

production of hypertension in man is the same as in experimental animals. Accordingly, when the patient was moribund, permission for autopsy was obtained and preparations were instituted for making and testing a perfusate of one of her kidneys as soon as possible following death. When it was apparent that the obstructing thrombus (with resultant infarction) extended only a short distance into the renal artery on the right side, this vessel was cannulated beyond the point of obstruction and the kidney removed for perfusion. The experiment was performed twenty minutes after death.

Procedure.—Fifty cc. of warm physiologic solution of sodium chloride was reperfused through the kidney five times. Twenty cc. of a bloody perfusate was obtained. This was tested by intravenous injection into a cat anesthetized with soluble pentobarbital, the blood pressure being recorded from the carotid artery in the usual manner.

Results.—Two cc. of perfusate had a prolonged pressor effect. The test animal was then given repeated injections of 4 cc. of the perfusate, with the result that rapidly decreasing pressor responses were obtained (fig. 3). Another cat was then given 5 mg. of cocaine, followed by another injection of the perfusate. There was no change in pressor response, proving that the pressor substance was not parahydroxyphenylethylamine.¹¹ The shape of the pressor curve and the duration of the pressor response were similar to those obtained by intravenously injected

11. Tainter, M. L., and Chang, D. K.: Antagonism of Pressor Action of Tyramine by Cocaine, 30: 193-207 (Jan.) 1927.

perfusate of completely ischemic kidneys of cats. Previous to this study we had tested perfusates from 4 fresh human kidneys, 2 of which were obtained immediately after death at autopsy and 2 following surgical removal. None of these perfusates which were prepared and tested in precisely the same manner as described exhibited a pressor effect.

COMMENT

The pressor substance found in perfusates of the ischemic kidney of the patient was similar to that present in perfusates of ischemic kidneys of animals because:

1. The pressor curves in the two were of similar configuration.

2. Both substances displayed the property of tachyphylaxis.

3. The pressor response was not altered by a previous injection of cocaine in either instance, excluding parahydroxyphenylethylamine as the cause for the hypertension.

4. Negative evidence is supplied by the fact that the pressor substance was not found in perfusates of nonischemic kidneys of either human beings or cats.

It will be recalled that when the patient was admitted to the hospital the blood pressure was normal and rose within the space of a few days to hypertensive levels and remained so until death. The postmortem examination not only confirmed the clinical impression of occlusion of both renal arteries but also excluded other possible causes for the sudden development of hypertension. It would appear, therefore, that this case furnishes a perfect example of hypertension following relatively acute renal ischemia in a human being. Since it has been proved that the pressor substance detected in perfusates of completely ischemic kidneys of cats is responsible for the postischemic hypertension in the Taquini experiments,⁷ the finding of the same pressor substance in perfusates of the patient's ischemic kidney strongly suggests that the mechanism responsible for the patient's hypertension was the same as that which obtains in the experimental animals. Whether or not this substance is responsible for other types of clinical hypertension remains for future studies to decide.

From the clinical point of view this case is also of interest because it serves as a reminder that renal infarction may be followed by hypertension. Statements are often made that hypertension does not occur under these circumstances; extremely few articles state that an elevation of blood pressure may follow renal infarction.¹²

SUMMARY

A patient suffering from chronic rheumatic heart disease became hypertensive within the space of a few days following an acute attack of severe abdominal pain. The elevation of blood pressure was accompanied by increasing suppression of urine short of complete anuria and by progressive nitrogen retention, and death occurred in uremia. At the postmortem examination there were found occlusion of both main renal arteries by thrombus formation, probably of embolic origin, and almost complete infarction of both kidneys. The train of events being identical with those occurring in the experimental production of hypertension, this case offers a perfect example in a human being of hypertension resulting from acute renal ischemia.

Perfusates that were prepared immediately after death from one of the infarcted kidneys revealed the presence of a pressor substance which is presumably the same as that responsible for the hypertension that follows the termination of complete renal ischemia in experiments on animals. Attention is called to hypertension as a neglected sign in occasional cases of renal infarction.

FIFTH ANNUAL SUMMARY OF FOURTH
OF JULY INJURIES

DUE TO FIREWORKS AND EXPLOSIVES

SECOND SERIES

In 1937 the American Medical Association resumed its annual summaries of injuries resulting from the celebration of the Fourth of July with fireworks. This report for 1941 is the fifth of the reports in the series. The second series constitutes a resumption of similar summaries which were published from 1903 to 1916 and discontinued thereafter because of the reduction in the number of such accidents. Unfortunately the great increase in fireworks injuries again made this problem a matter of serious public importance.

DEATHS

Eleven deaths were reported in 1941 as directly due to the celebration of the Fourth of July with fireworks or other explosives. The distribution by states in comparison with the figures for recent years is given in table 1. For the first time since 1937 the decline

in total number of deaths has been reversed. Eleven deaths were recorded in 1941 as compared with eight in 1940. It is also noteworthy that for the first time none of the fatalities were due to burns resulting from the igniting of clothing from fireworks. Three deaths occurred in Chicago, one from burns due to explosion of firecrackers, one in a small girl of 4 who bit into a torpedo and sustained extensive lacerations of the

face, and the third in a visitor from Iowa who received a bullet wound from a gun used in noise making activities. Two boys in Memphis, Tenn., died as the result of injuries sustained when another boy tossed a lighted firecracker into the counter of fireworks in

vision in one or both eyes and 104 sustained eye injuries. Nevertheless, as shown in table 2, there has been a decline in the total number of serious injuries.

INJURIES

Table 3 totalizes the injuries from firecrackers and other explosives in 1941 and in parallel columns the injuries recorded for the preceding four years. As has been pointed out in previous reports, these figures do not take into account hospitals which failed to report their accidents or injuries treated in physicians' offices. The totals, therefore, must be considered conservative and if all injuries were recorded the numbers would doubtless be considerably higher. The most striking figures in the report are those relating to New York State, where the injuries declined from over 1,100 in 1940 to 105 in 1941. This change unquestionably can be attributed to the state legislation, which first became effective on the Fourth of July of 1941. This year Ohio has the unenviable distinction of leading all states in the number of injuries, in spite of the fact that the total represents some decrease from previous years. Ohio is followed closely by California, Massachusetts and Illinois, in that order, all with bad records. Ohio passed an antifireworks bill to take effect August 1, 1941, which therefore was without value for this year. California has a limited law which was obviously not satisfactorily effective. In Massachusetts the antifireworks legislation was defeated. The large number of injuries in that state therefore can be directly attributed to failure to adopt legislation which was obviously

a shed from which the boys were selling. The other deaths resulted from a variety of accidents, including the premature explosion of a bomb in a fireworks display, a misdirected aerial bomb in another fireworks display, a gunshot wound, and an explosion which resulted while a bomb was being mixed.

TETANUS

There were 2 cases of tetanus in both 1937 and 1938. In 1939 none were reported and in 1940 there were 2. In 1941 1 case of tetanus was reported from Massachusetts. In this case clinical symptoms of tetanus began eight days after a firecracker wound on the leg. Despite antitoxin administration as soon as diagnosis was made, the patient died.

SERIOUS INJURIES

Hospital questionnaires and newspaper clippings again record numerous serious and unusual injuries resulting from firecrackers. Nine persons lost the

indicated by experience of previous years. A bill to control fireworks will become effective in Illinois on Jan. 1, 1942.

However, the state with the worst record as judged by the relation between the number of injuries and the size of the population is Rhode Island. The states with the largest percentage of increase in injuries from 1940 to 1941 are Connecticut from 48 to 81, South

Carolina from 0 to 4, Utah from 1 to 6 and Virginia from 11 to 18. Of these, apparently Utah is the only state with a satisfactory law on the books. Delaware is the only state which has had a perfect record of no injuries for the last two years. However, in 1941 Mississippi and Nevada did not record any fireworks accidents. Curiously, Tennessee recorded two deaths but no other fireworks injuries.

A striking improvement has occurred between 1940 and 1941 in Alabama, Arizona, Kansas, Kentucky, Maine, Nebraska, New Jersey and Oklahoma. Alabama, of course, as a Southern state, would be expected to have few fireworks accidents on the Fourth. The improvement in Arizona is probably due to the adoption of a control bill effective in 1941. The explanation for Kansas is unknown; Kentucky has a regulatory law. The excellent results obtained in Maryland are doubtless due to the adoption of a new law this year. No ready explanation for the improvement in Maine is available. Nebraska has had a law since 1937. New Jersey was one of the first states to adopt adequate legislation but showed from 1937 to 1940 a steady although slight rise in number of accidents, presumably due to laxity in enforcement. This year the trend has been strikingly reversed, and New Jersey shows the lowest number of injuries ever recorded for that state, this result being attributed in press releases to an embargo placed on all shipments of fireworks into the state and to the effectiveness with which the new law in New York was enforced. It is particularly noteworthy that Indiana, which had one of the worst records of any state up until the application of its antifireworks law in 1940, has for the last two years reported only three such accidents. Obviously, the states which need adequate state laws and enforcement most are Ohio, Massachusetts, Illinois and California. Of these Ohio and Illinois have laws which are to become effective for the Fourth of July 1942; it will be interesting to see how effective their enforcement will be. The record of Massachusetts with defeat of a satisfactory bill would imply an extraordinary lack of interest in the lives and limbs of its citizens.

Washington, D. C., leads the large cities in 1941 in the proportion of injuries per hundred thousand of population, displacing Baltimore, which, as a result of finally enacted and enforced legislation, no longer appears on the list of large cities with bad records. In table 4 appears a tabulation of the cities with the highest rates of injuries. It should be noted that four cities of intermediate size, two of them in Rhode Island, lead all the larger cities in rate of injuries per hundred thousand of population. It is noteworthy also that more than half of all the injuries which were reported in Connecticut occurred in one of its cities, Hartford.

This year hospitals were specifically instructed to list injuries from cap pistols separately, and these are given in table 5. Although this question was asked in 1940, comparable 1940 figures are not given since, because of the different method of collection, they presumably included some injuries from blank cartridges, guns and firecrackers. It is curious to note that, in spite of the small number of injuries, three were serious, in one case resulting in hospitalization for twenty-three days and in another for forty-two days. On close examination the majority of the injuries appeared to be due to the caps themselves rather than the normal use of the cap pistol.

COMMENT

As has been pointed out repeatedly in these reports, the reduction of fireworks injuries is dependent not only on adequate state legislation but on enforcement as well. In 1940 the state which demonstrated these points most dramatically was Indiana; this year Maryland and New York showed an enormous reduction in injuries. With the exception of most of the Southern states, which do not celebrate the Fourth of July with fireworks as pointed out recently in a letter from Mr. Bugbee, director of the National Fire Protection Association published in *THE JOURNAL*, there are few exceptions to the rule that only those states which have enacted and enforced statewide laws have shown evidence of satisfactory control. It is however a source of satisfaction that, in the five years since these reviews have been resumed, the total number of unnecessary accidents of this nature have declined from 7,205 in 1937 to 2,039 in 1941. This source of death and disfigurement can be still further reduced, especially by prompt enactment and enforcement of suitable legislation in those states, such as Massachusetts and Rhode Island, which do not have effective laws. Ohio and Illinois, if adequate enforcement is attained next year, should show considerable improvement. In view of the experience of the last two years the California legislation should receive prompt attention with a view to making it serve the purposes for which it was presumably intended.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS. HOWARD A. CARTER, Secretary.

ALLERGY ELECTRIC MASK NOT ACCEPTABLE

Manufacturer: Allergy Research Institute, Inc., P. O. Box 1399, Cincinnati.

The Allergy Electric Mask, a beak-shaped mask covering the nose and mouth, is claimed in the firm's advertising to be "An Advanced Scientific Treatment for Hay Fever—Rose Fever—Seasonal Asthma." It is said that the device ". . . will filter and purify the air inhaled by the wearer . . . 99.46% OF THE POLLENS AND MOLDS ARE REMOVED FROM THE AIR WITH THE ALLERGY ELECTRIC MASK." The perforated metal front rests on a rubber base which is fashioned to fit against the contour of the face; head straps hold the device in place.

In operation a mechanical method and an alleged electrical method of filtration are employed. The electric filter consists of two molded fine mesh metal screens, one attached to the negative and the other to the positive pole of a 1½ volt battery. The mechanical filter pad, a cellulose-sheet type filter, is placed between the two metal screens. Following is an excerpt from the firm's advertising:

The ALLERGY ELECTRIC MASK causes the air to flow through a circuit containing a positive-charged screen and a negative-charged screen. Those pollens having a positive electrical charge are repelled by the positive-charged screen, while pollens having a negative electrical charge are repelled by the negative-charged screen. (A pollen attracted to an opposite-charged screen immediately loses its own charge and assumes the same charge as that of the screen, and is then repelled.)

The Mask utilizes the electrical method of filtration to greatest advantage, because it contains a small battery which produces a complete electrical circuit about the filter pad. The positive pole of the battery, connected to a metal screen, gives this screen a positive charge. The negative pole of the battery, connected to the other screen, gives this other screen a negative charge. The filter pad lies between the two screens. As the air flows through the Mask, the harmful particles are removed by both mechanical and electrical methods of filtration.

The Council's investigation of the device brought forth the following results:

A series of exposures was made while the mask was worn by a patient for periods of a few hours each over a period of fifteen days. A petrolatum covered glass cover slip was placed both on the outside and on the inside of the mask and the number of pollens on the same area (usually 1.8 sq. cm.) were compared. The following results were obtained:

With Battery	Exterior	Interior
8/27	3	0
8/29	4	0
8/30	1	0
8/31	0	0
3/31	0	1
9/2	1	0
9/4	16	48
9/4	17	54
9/5	6	7
9/6	3	7
Without Battery	Exterior	Interior
9/7	18	11
9/8	15	17
9/9	1	2
9/10	0	1

In another experiment pollen was dispersed in a room by means of a fan and the mask with a cover slip on the outside, and one on the inside was worn by the experimenter for a period of thirty to sixty minutes. Pollen counts were then made as before, with the following results:

With Battery	Exterior	Interior
Experiment 1	58	82
Without Battery	Exterior	Interior
Experiment 2	142	121
Experiment 3	76	92

It is apparent not only that the filtering efficiency of the mask is poor but that the battery adds no advantage.

The Council voted not to include the Allergy Mask on its list of accepted devices because the claims made by the firm for the instrument were not substantiated by the Council's tests.

HAYRIN NASAL FILTER NOT ACCEPTABLE

Manufacturer: Allergy Research Institute, Inc., P. O. Box 1399, Cincinnati.

The Hayrin Nasal Filter is advertised as "A scientifically Designed and Specially Constructed (Invisible) Nasal Filter Which Will Aid in the Relief of Hay Fever, Rose Fever and Seasonal Asthma. . . ." It is manufactured and distributed by the firm manufacturing the Allergy Electric Mask and promotional matter from the firm states "The Allergy Electric Mask and the completely invisible Hayrin Nasal Filter make an ideal combination. The mask can be worn when sleeping, while driving, and when about the home; and the Filter can be worn at work, play and at social engagements."

Although the device was not submitted to the Council for consideration by the firm, the many inquiries coming to the office of the Council concerning the device made advisable the preparation of a report. The nasal filter was purchased and examined by the Council.

In the firm's promotional literature the device is claimed to "give an effect similar to carrying an air conditioning unit with you." The outfit consists of two silver frames into which are to be placed the filter pads. The frames are adjustable to varying sizes of nasal chambers. These filters are to be placed in the nose to filter out pollen, molds and other dust particles.

Many misleading statements and unjustifiable claims are made in the advertising and in the correspondence to a prospective purchaser. The filtering device is uncomfortable when fitted in the nose. Dry pollen placed on the filter pad did not go through the mesh. However, when such a pad is moistened with secretions it acts not only as an obstacle to pollen but also as an obstruction to the free entrance of air. Although the filter may stop pollen from entering the nose, it cannot prevent the entrance of pollen through the mouth and eyes. While such filters have in some instances improved the nasal symptoms they have not prevented, indeed have even favored, the occurrence of asthma.

The Council voted not to include the Hayrin Nasal Filter on its list of accepted devices.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

THEODORE G. KLUMPP, M.D., Secretary.

LIVER PURIFIED SOLUTION-DRUG PRODUCTS CO., INC.—A sterile aqueous, clear, dark brown solution containing all of the fraction G of the liver extract (Cohn), preserved with 0.5 per cent of carbolic acid (phenol). The daily parenteral administration of 0.1 cc. has been found to produce the standard reticulocyte response defined as 1 U. S. P. unit (injectable) when assayed in cases of pernicious anemia as required by the Council.

Actions and Uses.—Liver purified solution-Drug Products Co., Inc., is recommended for intramuscular use in the treatment of pernicious anemia. See the general article Liver and Stomach Preparations (New and Nonofficial Remedies, 1941, p. 328).

Dosage.—For the average case in relapse, 10 U. S. P. injectable units (1 cc.) may be injected as the initial dose. Subsequent doses from 5 to 10 U. S. P. injectable units (0.5 to 1.0 cc.) may be given weekly until the blood picture has returned to normal. The maintenance dose should be not less than 1 U. S. P. injectable unit (0.1 cc.) daily and should be adjusted to the needs of the individual patient depending on the degree of complications. It may be administered at weekly or longer intervals in equivalent cumulative doses.

Distributed by Drug Products Co., Inc., Long Island City, N. Y.
Hyposols Liver Purified Solution-Drug Products Co., Inc., 1 cc. (10 U. S. P. injectable units per cubic centimeter).
Vials Liver Purified Solution-Drug Products Co., Inc., 10 cc. (10 U. S. P. injectable units per cubic centimeter.)

Liver purified solution-Drug Products Co., Inc., 10 units per cubic centimeter, is prepared as follows: Fresh edible liver is extracted with water at 170 F. for thirty minutes and filtered. The filtrate is concentrated in vacuo and extracted with 70 per cent alcohol; the alcoholic extracts are concentrated in vacuo and precipitated with ammonium sulfate. The precipitate is further purified by alcoholic fractionation, the alcohol removed and the extract made up to volume so that each cubic centimeter contains the extract from 100 Gm. of fresh liver. Fifteen per cent phenol is used as a preservative.

SOLUTION OF POSTERIOR PITUITARY (See New and Nonofficial Remedies, 1941, p. 395).

PITUITARY SOLUTION-U. S. P. (LAKESIDE).—A brand of solution of posterior pituitary-U. S. P.

Manufactured by Lakeside Laboratories, Inc., Milwaukee.
Ampul Pituitary Solution-U. S. P., 0.5 cc. (Lakeside).
Ampul Pituitary Solution-U. S. P., 1 cc. (Lakeside).
Vials Pituitary Solution-U. S. P., 10 cc. (Lakeside).
Vials Pituitary Solution-U. S. P., 30 cc. (Lakeside).

ALUMINUM HYDROXIDE GEL (See THE JOURNAL, Nov. 1, 1941, p. 1539).

Aluminum Hydroxide Gel-Schieffelin.—A brand of aluminum hydroxide gel-N. N. R. The preparation contains 5.5 per cent aluminum hydroxide (equivalent to 3.3 per cent aluminum oxide). Saccharin and Oil of Peppermint U. S. P. are added as flavoring agents. Marketed in bottles of 1 pint and 1 gallon.

Manufactured by Schieffelin & Co., New York. No U. S. patent or trademark.

MERCURIC SALICYLATE (See New and Nonofficial Remedies, 1941, p. 349).

Cheplin Biological Laboratories, Inc., Syracuse, N. Y.

Bottles Mercuric Salicylate, 1 grain (0.065 Gm.) Suspended in Oil, 60 cc. Each cubic centimeter contains mercuric salicylate 1 grain (0.065 Gm.), quinine and urea hydrochloride 0.005 Gm., wool fat 0.1 Gm., double distilled water 0.05 cc. and Wesson oil (corn oil) to make 1 cc.

NICOTINIC ACID (See New and Nonofficial Remedies, 1941, p. 555).

The following dosage forms have been accepted:

Tablets Nicotinic Acid, 20 mg., 100 mg.

Prepared by George A. Breon & Company, Inc., Kansas City, Mo.

SULFANILAMIDE (See New and Nonofficial Remedies, 1941, p. 506).

The following dosage forms have been accepted:

Tablets Sulfanilamide, 2½ grains, 5 grains, 7½ grains.
Prepared by McNeil Laboratories, Inc., Philadelphia.

535 NORTH DEARBORN STREET - - - CHICAGO, ILL.

Cable Address - - - "Medic, Chicago"

Subscription price - - - - Eight dollars per annum in advance

Please send in promptly notice of change of address, giving both old and new, always state whether the change is temporary or permanent. Such notice should mention all journals received from this office. Important information regarding contributions will be found on second advertising page following reading matter.

SATURDAY, JANUARY 3, 1942

A CALL TO THE MEDICAL PROFESSION

Last week The Journal published an enrolment form for the Procurement and Assignment Service for Physicians. Already many physicians have sent this blank directly to the headquarters of the Procurement and Assignment Service in Washington. On the opposite page appears another copy of the enrolment form. EVERY PHYSICIAN IN THE UNITED STATES WHO HAS NOT YET SENT THIS FORM TO THE EXECUTIVE OFFICER IN WASHINGTON SHOULD DO SO AT ONCE.

The only way in which the Procurement and Assignment Service can function to supply the Army, Navy and Public Health Agencies with the necessary personnel and to make sure that civilian and industrial needs are suitably cared for is to have the complete cooperation of the medical profession. FILL OUT THE BLANK ON THE OPPOSITE PAGE, TEAR IT OUT OF THE JOURNAL AND SEND IT AT ONCE TO DR. SAM F. SEELEY, EXECUTIVE OFFICER OF THE PROCUREMENT AND ASSIGNMENT SERVICE.

If you have already sent in the blank published last week, make certain that some other physician who may not have received a blank does the same. Ask your professional colleagues whether or not they have enrolled. If they have not yet enrolled, tell them to send in the blank which is made available through The Journal of the American Medical Association or through a state medical journal and offer them the extra blank published in this week's issue if they do not have one available.

MECHANISM OF ANTIPNEUMOCOCCUS SERUM THERAPY

Studies of the cytologic mechanism of spontaneous recovery from experimental pneumococcal pneumonia in rats and modification of this mechanism under the influence of type specific antiserum are currently reported by Wood¹ of the department of bacteriology and immunology at the Harvard Medical School. Since experimental pneumococcal pneumonia in rats closely simulates human lobar pneumonia, the results of the investigation are presumably applicable to clinical medicine. Previous studies of clinical and experimental pneumococcal pneumonia have led to numerous contradictions and inconsistencies. Fully encapsulated living pneumococci are recognized to be resistant to attack by phagocytic cells unless previously sensitized with specific antibodies.² Nevertheless, investigators have shown that complete recovery may occur both in man and in laboratory animals long before specific antibodies can be demonstrated in the circulation.³ Well supported laboratory and clinical evidence indicates that intravenous injection of specific antiserum often brings about a rapid recovery, yet much evidence has been advanced that specific antibodies cannot penetrate the pneumonic lung.⁴ To complicate matters, quantitative data indicate that, were antibodies able to enter the pulmonary alveoli, they could not accumulate in sufficient amounts to neutralize the antiphagocytic type specific polysaccharide there present. Nye and Harris,⁵ for example, estimate that at least 60 liters of the highly potent type I antiserum would be necessary to precipitate completely the inhibiting pneumococcus carbohydrate. Drugs of the sulfapyridine group are not bactericidal in concentrations usually employed in clinical medicine; nevertheless, following treatment with sulfapyridine, patients often recover without the aid of circulatory antibodies.⁶

In order to settle these and other controversial questions, Wood made a detailed microscopic study of the evolution of experimental pneumococcal pneumonia in rats. By means of an adaptation of the technic of Jourdonais and Nungester⁷ the rats were inoculated by intrabronchial injection of 0.1 cc. of 6 per cent mucin containing from 4,000 to 7,000 highly virulent type I pneumococci. To insure alveolar penetration of the inoculum, the rats were hung in a vertical position by the upper incisor teeth for thirty minutes while still under light ether anesthesia.

The pneumococcal pneumonia produced by this technic is uniformly fatal. All 40 untreated control rats

ENROLMENT FORM FOR PROCUREMENT AND
ASSIGNMENT SERVICE FOR PHYSICIANS

Dr. Sam F. Seeley, Executive Officer
Procurement and Assignment Service
New Social Security Building
4th and C Streets S.W.
Washington, D. C.

Dear Doctor Seeley:

Please enroll my name as a physician ready to give service in the Army or Navy of the United States when needed in the current emergency. I will apply to the Corps Area commander in my area when notified by your office of the desirability of such application.

Signed _____

1. Give your name in full, including your full middle name:
2. The date of your birth:
3. The place of your birth:
4. Are you married or single?
5. Have you any children? If so, how many?
6. Do you believe yourself to be physically fit and able to meet the physical standards for the Army and Navy Medical Corps?
7. Have you filled out previously the questionnaire sent to all physicians by the American Medical Association?
8. When and where were you graduated in medicine?
9. In what state are you licensed to practice?
10. Do you now hold any position which might be considered essential to the maintenance of the civilian medical needs of your community? If so, state these appointments:
11. Have you previously applied for entry into the Army or Navy Medical Service? If so, state when, where and with what result (if rejected, state why).

succumbed to the disease in less than five days, the majority dying in about forty-eight hours. Necropsies showed consolidation of the lobar type, usually with an accompanying pleurisy, pericarditis and bacteremia.

To study the evolution of the pulmonary lesion, groups of 5 untreated rats were killed at the end of twenty minutes, two hours, six hours, twelve hours, eighteen hours, twenty-four hours and thirty-six hours after inoculation. Their inflated lungs were fixed *in situ*. A composite picture of all groups showed a small circumscribed area of consolidation in the injected pulmonary lobe at the end of two hours, increasing to an involvement of the entire lobe by the end of thirty-six hours. Three definite histologic zones could be recognized in this spreading lesion: First there was an advancing outer zone characterized by the presence of edema fluid in the alveoli. This edema fluid contained few if any leukocytes but did contain innumerable pneumococci, which apparently multiplied freely in this favorable medium. Outward mechanical flow of this infected edema fluid was apparently the main mechanism of spread of the pulmonary lesion.

Inside this peripheral zone there was a second zone in which the alveoli contained both leukocytes and micro-organisms. In the outer portion of this intermediate zone, where the leukocytes were relatively few, pneumococci were numerous. In the inner portion the leukocytes dominated and bacteria were scarce. Phagocytosis of the pneumococci by polymorphonuclear leukocytes was a conspicuous feature of this portion, even though specific opsonins were not demonstrable at this stage. Finally there was an inner zone of advanced consolidation characterized by the complete absence of organisms, the alveoli being packed with leukocytes and fibrin deposits being occasionally observed. In the older parts of the consolidated area, macrophagic resolution had already begun.

The histopathology of the forty-eight hour lungs was essentially the same, except that by this time the lesion had usually extended to adjacent lobes. In all stages the essential site of the spreading infection was in the outer edema zone, with complete or practically complete leukocytic sterilization in the consolidated areas. To explain this phagocytosis it must be assumed either that specific opsonins are formed locally in the infected tissues⁸ or that there are unknown local hormonal or enzymic factors making possible adequate phagocytosis in the absence of specific opsonins.

Turning now to a study of the therapeutic effects of specific antiserum, Wood treated groups of infected rats with homologous type-specific antipneumococcus serum. Deaths did not occur among the 76 rats treated within

eighteen hours after intrabronchial inoculation. Conditions in animals killed from four to seven days later indicated in each case that the pneumococcal infection had completely subsided. To determine the mechanism of this therapeutic recovery, groups of treated animals were killed at various times after treatment. Within six hours after peripheral injection of the antiserum the spreading lesion was arrested, the outward margin becoming sharply demarcated. Within one hour after injection of the antiserum the pneumococci of the edema zone could be seen to be agglutinated and firmly adherent to the alveolar walls. By the end of six hours, practically all of the extracellular organisms of this zone had congregated into large immobilized clumps. This included pneumococci in large bronchi as well as within the alveoli. The clumped cocci often showed capsular swelling. Accelerated phagocytosis was noted in all cases. The essential mechanism of the therapeutic arrest is therefore apparently agglutination and immobilization of the pneumococci by alveolar adhesion, presumably due to specific epithelial opsonins analogous to the "endothelial opsonins" of earlier investigators.⁹ This peripheral immobilization apparently allows the micro-organism to be overtaken and destroyed by the advancing leukocytes. Within forty-two hours practically all pneumococci had been engulfed and completely digested by the phagocytic cells.

In contrast to this favorable action, Wood found that, if the administration of specific antiserum was delayed more than twenty-four hours after intrabronchial inoculation, nearly half of the treated animals died within eighteen hours, some of them even during the course of the serum injection. A definite explanation of this therapeutic shock is not suggested, though the animals evidently died of an anaphylactic-like reaction. Each rat showed evidence of pulmonary edema at the time of death, frothy hemorrhagic fluid exuding from the nostrils.

It has been suggested¹⁰ that, owing to its relatively small molecular diameter, rabbit antibody would presumably penetrate lung tissues more readily than horse serum. Wood found antipneumococcus horse serum equally effective with rabbit antiserum. Microscopic examination of type I pneumococcal lungs treated with type II antisera showed that heterologous antibody is without demonstrable therapeutic effect. Preliminary experiments have already shown that sulfapyridine causes a similar peripheral immobilization of pneumococci, though the mechanism of this immobilization is apparently different from that with specific antiserum. Further studies of this chemotherapeutic peripheral immobilization are now in progress in the Harvard laboratories.

Current Comment

OPPORTUNITIES FOR PHYSICIANS

Much has been said about the rapid advance of medical science and the relatively slower march of medical practice—the lag between the acquisition of knowledge and its utilization. In order to shorten the time required for dissemination throughout the profession of information concerning the practical application of the newest discoveries and the latest improvements in the technic of diagnosis and treatment, a network of continuation courses for practicing physicians has been established under the auspices of medical societies, health departments, medical schools, hospitals and other agencies. Varying widely in methods employed, time involved and geographic distribution, these courses are designed to increase the knowledge and skill of those responsible for the care of the sick. For those who would avail themselves of these opportunities, the Council on Medical Education and Hospitals has compiled and publishes in this issue of *THE JOURNAL* a classified list of courses of five days' duration or longer which will be offered during the next three months. The number and the scope of these offerings present substantial evidence that the medical profession is alive to its responsibilities.

DETECTION OF EARLY OCULAR CHANGES IN AVITAMINOSIS A

Assessment of the nutritional status of human beings has long been a subject of study; particularly, in recent years, new methods and technics have been devised and older ones improved to provide more accurate means of evaluation. Early recognition of impairment due to dietary deficiencies is important. Kruse¹ recommends a biomicroscopic ocular examination as a simple and objective method for the detection of xerosis conjunctivae, an early sign of vitamin A deficiency. An application of this type of study to a hundred and fifty adults from a low income group showed that in 45 per cent of the subjects ocular manifestations in the form of characteristic elevated conjunctival spots, which are a feature of advanced xerosis conjunctivae, could be detected by gross examination. Another 54 per cent had microscopic ocular lesions characteristic of avitaminosis A. Vitamin A therapy effected complete disappearance of the conjunctival lesions in some of the patients; in all others who were still receiving vitamin A at the time of the report the lesions had receded to the point of near disappearance. Months of therapy, however, were required to effect complete recovery. As interpreted by Kruse, the results of this limited survey revealed an unusually high prevalence of avitaminosis A in a low income group. The question arises concerning the relative value of this examination as compared with

others depending on a measurement of dark adaptation.² Fortunately, a study on the correlation of conjunctival lesions with dark adaptation has been carried out, and a report of this work is forthcoming. Pertinent is the suggestion of Kruse that xerosis probably precedes night blindness as an early sign of avitaminosis A. Further research will undoubtedly elucidate this important point and will contribute to the broader problem of the early detection of avitaminosis A.

MERCURIALISM IN THE FELT HAT INDUSTRY

A solution containing mercury has long been used to treat fur in order to make it amenable to felting. In this "carroting" process part of the metal enters into chemical combination with the fur, from which it then gradually volatilizes into the air as elemental mercury. A serious health hazard is thus created. A recent survey by the U. S. Public Health Service revealed that over 10 per cent of a group of several hundred hatters examined were suffering from chronic mercurialism, a syndrome which is characterized by fine intention tremor, psychic irritability of an exaggerated degree, exaggerated tendon reflexes, pallor, and certain abnormalities of the mouth, among other symptoms.¹ A serious effort has been made to eliminate the use of mercury in the treatment of fur by the development of mercury free agents. Of interest in this connection is a report by Beal, McGregor and Harvey² in which is described the theoretical and the practical work culminating in the successful use of nonmercurial carroting materials. From the end of 1936 to September 1941 some 2,000,000 pounds of fur was carroted with these agents and in 1941 alone it may be estimated that 1,500,000 pounds was thus treated. Owing to the introduction of carrots free from mercury, it seems possible that mercurialism may in the future be entirely banished from the felt hat industry. This development has been greatly assisted by the industry itself. Investigations which have resulted in the development of nonmercurial carroting agents were promoted by the industry through the establishment of a fellowship at the Mellon Institute—an excellent illustration of how planned research may help to eliminate industrial health hazards. While we can look forward to the day when the felt hat industry is no longer plagued with occupational disease, the danger is present wherever mercury is handled. In any case, however, the mercury hazard can be minimized by following the suggestions of the bureau of public health, which recommends the segregation of sources of volatile mercury and ventilation so arranged as to minimize exposure of workers to mercury vapor.¹

MEDICAL PREPAREDNESS

In this section of The Journal each week will appear official notices by the Committee on Medical Preparedness of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medical preparedness, and such other information and announcements as will be useful to the medical profession.

CAMPAIGN FOR CORRECT DIET FOR CIVILIAN DEFENSE

Representatives of the federal government, the municipal health department, the organized medical, dental and nursing professions, food industries and welfare agencies addressed a meeting in the Health Building, New York City, December 10, which opened a campaign to encourage the use of correct diets as an essential phase of civilian defense. The health commissioner of New York City, Dr. John L. Rice, who presided, said that the principal objectives of the program were to see that no one lacks sufficient food; second, that the wastage of food in homes and restaurants be stopped, and, third, to prevent the hoarding of food. The acting mayor, Newbold Morris, pointed out that the problem was mainly one of education and recommended as educational material a booklet prepared for distribution by the city health department entitled "Food Joins the Colors." Dr. W. H. Sebrell, deputy assistant director of the Federal Security Agency in charge of nutrition, pledged the support of various coordinating bureaus of the federal government in the nutrition program in the various cities. Assistant Superintendent of Schools William Jansen said that plans had already been worked out for the mass feeding of children that might have to leave New York City. Deputy Welfare Commissioner Leo Arnstein said that his department aided the needy to get proper diet not only by direct cash assistance but also through three thousand investigators of the department giving clients on relief advice on nutrition. City Markets Commissioner William F. Morgan Jr. said that no bombing of the New York City area would cause serious food shortage, as the most exact information exists on what food and how much is handled at each market and depot, and preparations have been made to reroute food deliveries in case of bombings. Among the other speakers were Dr. Maximilian A. Ramirez, president-elect of the New York County Medical Society; Dr. Adam Eberle, general medical superintendent of the hospitals department; Dr. John O. McCall, director of the Guggenheim Dental Clinic, and Clarence Francis, president of the General Foods Corporation.

RECREATION CENTERS AND SERVICE CLUBS

The army has built one hundred and nine service clubs on military reservations throughout the country to provide the recreation and social advantages of a men's club for enlisted personnel; twenty-two others are under construction, while ninety-three guest houses are already operating and nineteen others have been authorized. These clubs are designed for recreational reading, refreshments, musicals, parties, dances and as a meeting place for enlisted men, their families and friends. Accommodations for overnight guests and quarters for hostesses are furnished in guest houses constructed nearby as an adjunct to the service clubs, which are of three general types, depending on the size of the garrison. The largest type club has three hostesses and one librarian. An allotment of \$10,500 was made to equip each of the medium sized (SC-4) clubs. Guests occupying the guest houses are charged a nominal sum to defray the cost of laundering linens and necessary housekeeping service. The usual cost per person is 50 cents a night.

Paul V. McNutt, director of defense health and welfare services, announced on November 28 completion of construction at Fayetteville, N. C., of the first two of several hundred service men's recreation centers. The Fayetteville centers are among the two hundred and seventy-three constructions and renovations being provided with federal money through the Community

Facilities Act, in communities near army camps and naval posts, almost all of which were to be finished by New Year's. Fayetteville, with a normal population of 18,000, is 10 miles from Fort Bragg, where the garrison amounts to nearly seventy thousand; during the maneuvers about one hundred and twenty thousand soldiers were in that area. The Fayetteville Defense Recreation Council, cooperating with the Federal Security Agency, has undertaken to coordinate community recreation, utilizing facilities in schools, churches and private homes, which, however, in themselves were insufficient.

UNNECESSARY AMBULANCE CALLS AND THE SHORTAGE OF INTERNS

The commissioner of hospitals of New York City, Dr. Willard C. Rappleye, announced on Dec. 21, 1941 that it probably would be necessary in the near future to discontinue interns on the ambulances of the voluntary and municipal hospitals, owing to the increasing shortage of interns. Because of the need of medical officers for the expanding army and navy, many interns will be called to military duty.

Under the plan contemplated, trained attendants competent to deal with first aid and emergency care will be provided on each ambulance. All patients requiring diagnosis or medical attention will be promptly brought to the hospital, where they will be seen in the emergency ward and proper diagnosis and treatment established. Those who require hospitalization will be admitted; those who require only temporary care will be kept in the emergency ward until they can be discharged.

Dr. Rappleye stated that the Department of Hospitals and the voluntary institutions have for months been working on plans to provide trained ambulance attendants to take the place of interns on ambulances. In most large cities the ambulance service is manned by nonmedical personnel. At present in New York City less than half of the ambulance calls are for emergencies; many of the calls are for medical attention in the home or for minor injuries which could be taken care of in an outpatient department or by a neighborhood physician. Commissioner Rappleye appeals to individuals, families and community organizations to cooperate by going to private physicians or to outpatient departments and hospitals for medical attention rather than calling ambulances to their homes for ordinary illnesses or minor complaints.

The program now being studied would not change the medical and nursing personnel in the eighty emergency units now organized throughout the city that are standing by for any major catastrophe in the community.

LABORATORY AIDS IN DIAGNOSIS OF NEUROTROPIC VIRUS DISEASES

An item was printed in this section of THE JOURNAL, November 8, page 1631, concerning laboratory aids in the diagnosis of neurotropic virus diseases. In this circular letter from the Office of the Surgeon General, U. S. Army, it was stated that the Virus Laboratory of the Army Medical School would undertake to perform special diagnostic tests on specimens submitted from the field. It is apparent now that civilian physicians and hospitals gained the impression that this army laboratory service would be available for their use, as numerous requests from these sources for further information about this service has been received at the Army Medical School. The Surgeon General's Office desires to announce that this special laboratory service cannot be made available to civilians at this time.

ARMY RESERVE OFFICERS ORDERED TO ACTIVE DUTY

SIXTH CORPS AREA

The following additional medical reserve corps officers have been ordered to extended active duty by the Commanding General, Sixth Corps Area, which comprises the states of Wisconsin, Illinois and Michigan:

ALPNER, Sam, 1st Lieut., Battle Creek, Mich., 1609th Corps Area Service Unit, Fort Custer, Mich.
DOLAN, Patrick T., 1st Lieut., Pittsfield, Ill., 5th Division, Fort Custer, Mich.
GOODMAN, Daniel H., 1st Lieut., Galesburg, Ill., Reception Center, Camp Grant, Ill.
HERBERT, Walter N., 1st Lieut., Yale, Mich., Reception Center, Fort Custer, Mich.
KANTER, Lester, 1st Lieut., Chicago, 5th Infantry Division, Fort Custer, Mich.
KETTERER, Francis H., 1st Lieut., Breese, Ill., Reception Center, Scott Field, Ill.
KOVEN, Arthur Jerome, 1st Lieut., Maywood, Ill., Reception Center, Fort Custer, Mich.
LEAVITT, Arnold H., 1st Lieut., Chicago, Reception Center, Fort Custer, Mich.
MUNCH, Robert F., 1st Lieut., Chicago, Reception Center, Camp Grant, Ill.

POMARANC, Mark M., 1st Lieut., Chicago, Station Hospital, Camp McCoy, Wis.
PUTRA, Anthony Marion, 1st Lieut., Detroit, 33d Division, Camp Forrest, Tenn.
REID, Stephen E., 1st Lieut., Chicago, Station Hospital, Camp Grant, Ill.
ROBBINS, Fred Phillip, 1st Lieut., Chicago, Will Rogers Field, Oklahoma City.
WEISBERG, William Wiener, 1st Lieut., Chicago, Reception Center, Scott Field, Ill.
WINSAUER, Henry John, 1st Lieut., Kohler, Wis., Fred Harman, Ballinger, Texas.
YESINICK, Louis, 1st Lieut., Chicago, 1609th Corps Area Service Unit, Fort Custer, Mich.
ZIMMERMAN, Nathan, 1st Lieut., Chicago, Parks Air College, East St. Louis, Ill.

Orders Revoked

ESPENSCHIED, John S., 1st Lieut., Danville, Ill., Parks Air College, East St. Louis, Ill.
LEPPERT, Charles L., 1st Lieut., Rockford, Ill., Reception Center, Camp Grant, Ill.

SEVENTH CORPS AREA

The following additional medical reserve corps officers have been ordered to extended active duty by the Commanding General, Seventh Corps Area, which comprises the states of North Dakota, South Dakota, Minnesota, Nebraska, Iowa, Kansas, Missouri, Arkansas and Wyoming:

HARVEY, George, Jr., 1st Lieut., Rochester, Minn., Corps Area Service Command Station Hospital, Fort Snelling, Minn.
JERNIGAN, James Powell, 1st Lieut., Little Rock, Ark., Corps Area Service Command Station Hospital, Camp J. T. Robinson, Ark.
MILLER, Richard White, 1st Lieut., Fayetteville, Ark., Corps Area Service Command Station Hospital, Camp J. T. Robinson, Ark.
OTTEN, Donald Earnest, 1st Lieut., Minneapolis, Corps Area Service Command Induction Station, Fort Snelling, Minn.

REDMOND, William Storey, 1st Lieut., St. Joseph, Mo., Corps Area Service Command Station Hospital, Fort Leonard Wood, Mo.
STUMP, Robert Byron, 1st Lieut., Iowa City, Corps Area Service Command Station Hospital, Fort Leonard Wood, Mo.
SWANSON, Vincent Francis, 1st Lieut., Rochester, Minn., Corps Area Service Command Station Hospital, Fort Snelling, Minn.

Orders Revoked

STAUFFER, Harry B., Major, Jefferson City, Mo., Station Hospital, Camp J. T. Robinson, Ark.

Relieved from Active Duty

CHUNN, Stanley Sylvester, 1st Lieut., Pipestone, Minn., Fort Omaha, Neb.
SMAZAL, Stanley Francis, 1st Lieut., Davenport, Iowa, Fort Des Moines, Iowa.

NINTH CORPS AREA

The following additional medical reserve corps officers have been ordered to extended active duty by the Commanding General, Ninth Corps Area, which comprises the states of Washington, Montana, Oregon, Nevada, Utah, California and Idaho:

ANDERSON, Edward R., 1st Lieut., Tacoma, Wash., Fort Lewis, Wash.
BELL, Lloyd T., 1st Lieut., Culver City, Calif., Camp Callan, Calif.
BROOKE, Joseph M., 1st Lieut., Ronan, Mont., Station Hospital, Fort Lewis, Wash.
CHONG, Harry S., 1st Lieut., Sacramento, Calif., West Coast Air Corps Training Center, Moffett Field, Calif.
COHEN, Sidney, 1st Lieut., Provo, Utah, 7th Division, Fort Ord, Calif.
HAMILTON, Robert L., Captain, Marysville, Calif., Camp San Luis Obispo, Calif.
HARRIS, Chester S., Colonel, San Francisco, Recruiting and Induction Board, San Francisco.
JACOBSON, Hjalmer A., Captain, Fresno, Calif., Camp Roberts, Calif.

KAY, Raymond M., 1st Lieut., Van Nuys, Calif., Letterman General Hospital, San Francisco.
OWYANG, Edwin, 1st Lieut., San Francisco, Medical Replacement Training Center, Camp Grant, Ill.
SAYLIN, Joseph, Colonel, Pacific Palisades, Calif., Camp Roberts, Calif.
WENDLE, Cornelius C., 1st Lieut., Sandpoint, Idaho, Station Hospital, Fort Lewis, Wash.

Relieved from Active Duty

CLOTHIER, William L., 1st Lieut., Camp Callan, Calif.
COLLINGS, Maurice M., 1st Lieut., Fresno Air Base, Calif.
FISHER, Louis J., 1st Lieut., 53d Evacuation Hospital, Camp San Luis Obispo, Calif.
GARDENIER, William H., 1st Lieut.
GOURSON, Nathaniel E., 1st Lieut.
KOSTICHEK, Robert J., 1st Lieut., 7th Division, Fort Ord, Calif.
McDONALD, John B., 1st Lieut., Camp San Luis Obispo, Calif.
MILLER, Ernest C., 1st Lieut., McChord Field, Wash.
SASLAW, Lewis B., Captain.

ORDERED TO FOREIGN DUTY

BARALD, Fred Charles, 1st Lieut., New Haven, Conn., Station Hospital, Losey Field, Ponce, Puerto Rico.
BELZ, Joseph Aloysius, Captain, 25th Division Artillery Dispensary, Schofield Barracks, Honolulu, Hawaii.
BRENNAN, John James, 1st Lieut., Post of Manila, Manila, Philippine Islands.
CHESLER, William, 1st Lieut., Philadelphia, 70th Medical Battalion, Fort Clayton, Canal Zone.
CORRADO, Albert Guy, 1st Lieut., Connellsville, Pa., Fort Amador, Balboa, Canal Zone.
COUNTER, Henry Milton, 1st Lieut., Ladd Field, Fairbanks, Alaska.
CULVER, Wesley Youngs, 1st Lieut., Westhampton Beach, N. Y., Fort Clayton, Canal Zone.
DAY, Romney Maxwell, 1st Lieut., Albrook Dispensary, Albrook Field, Canal Zone.
DETER, Dwight Meyer, Captain, Austin, Texas, Station Hospital, Fort Mills, Corregidor, Philippine Islands.
FLAIG, Julian Vincent, Captain, Station Hospital, Schofield Barracks, Honolulu, Hawaii.
GLUCKFELD, Jerome Phillip, 1st Lieut., San Francisco, Fort Richardson, Alaska.
GOLD, Jacob Louis, Captain, Brooklyn, Schofield Barracks, Honolulu, Hawaii.

GOLDBERG, Joseph Dancis, 1st Lieut., New York, Station Hospital, Schofield Barracks, Honolulu, Hawaii.
GROSSMAN, Aaron, Captain, Department Training Center, Rio Hato, Albrook Field, Canal Zone.
HAYNES, Henry Matthais, Jr., 1st Lieut., Gatesville, Texas, Yakutat Landing Field, Yakutat, Alaska.
JONES, Leonard Bonham, 1st Lieut., Taft, Texas, Station Hospital, Fort Greely, Kodiak, Alaska.
KENDIG, Tom Atkins, 1st Lieut., San Antonio, Texas, Station Hospital, Fort Greely, Kodiak, Alaska.
KRAJESKI, Romuald John Frank, 1st Lieut., Wilkes-Barre, Pa., Panama Canal Department, Quarry Heights, Balboa Heights, Canal Zone.
MORTON, John Buck, 1st Lieut., Gray, Ga., Department Training Center, Rio Hato, Balboa Heights, Canal Zone.
MUSSELMAN, Merle McNeil, 1st Lieut., Omaha, Station Hospital, Fort Stotsenburg, Philippine Islands.
NICOSIA, Ralph Vincent, 1st Lieut., Houston, Texas, Tripler General Hospital, Honolulu, Hawaii.
TOWNSEND, Frank Marion, 1st Lieut., Harwood, Texas, Panama Coast Artillery Command, Fort Amador, Balboa, Canal Zone.
WANNER, Jay George, Captain, Medical Detachment, 2d Battalion, 37th Infantry, Fort Greely, Kodiak, Alaska.

ORGANIZATION SECTION

MEDICAL ECONOMIC ABSTRACTS

REAL LIFE TABLES EXCEED HYPOTHETICAL

In 1922 and again in 1933 the Metropolitan Life Insurance Company prepared hypothetical life tables to show where improvement in mortality might be expected. The census bureau has now issued a similar table based on the experience of white females in the general population of the United States for the period 1930 to 1939. The remarkable fact is that this table, based on actual experience, is almost identical with the hypothetical ones prepared almost twenty years earlier. "Except for the first year of life and at ages 50 and 60," says the Metropolitan Statistical Bulletin for November 1941, "the actual death rates for white females in 1930-1939 proved to be lower than in the hypothetical table of 1922. Thus have the hopes of the hypothetical table been not merely realized but surpassed by actual experience—and all this within two decades."

Another hypothetical table was prepared in 1933 based essentially on certain assumed reductions from the mortality of New Zealand females for 1931. Already actual experience is surpassing this new hypothetical table in some respects. "We have reason to believe," says the Bulletin, "that when all the data from our 1940 census are in it will be found that large sections of this country, principally in the Midwest, have mortalities as favorable as those of New Zealand." A new hypothetical table is again being prepared which starts with an expectation of life at birth of 70.78 years.

EXPLOITING MEDICAL SERVICE PLANS

The British Columbia Medical Association has for some time operated a prepayment plan much like the plans conducted by several of the state medical associations in the United States. Contracts have been made with industrial and other groups and the physicians have agreed to accept a reduction of 25 per cent from their regular fee schedules in payment for services rendered to those enrolled under the plan.

Within recent months, according to the Bulletin of the Vancouver Medical Association for November 1941, a number of quasi-insurance companies with various names have arisen. These undertake the sale of policies purporting to insure the beneficiary against the costs of sickness. When the patient has had an operation, the bill is sent to the patient for the full amount of the regular fee schedule. The organization then deducts 25 per cent of this bill and sends a check for the remainder to the physician. There is no contract between these companies and the medical association to accept any such reduction in fees. While the contracts with groups under the medical association plan cover all medical services, these company plans pay only for surgical operations.

The Bulletin comments on this situation as follows:

A very serious point for us to consider is that by accepting these people and their terms we are allowing a very dangerous principle to be introduced into the practice of medicine: this is third party gain. It is a dangerous principle that a third party should make money out of the sick and squeeze out of both the sick and the doctors attending them profit which they have not earned. Our Medical Services Association exists, and we should urge people to join this. It gives infinitely more value for their money and is under close supervision and control.

The modus operandi of these gentry is to send a curtailed check and, if the doctor protests, to utter all sorts of threats of blacklisting, etc., as well as to assure the doctor that every one else is accepting the cut. We think that the only answer to this sort of blackmail is to insist firmly on payment of our bill and ignore completely their threats. If we tell our patients the facts and show them where they can get equitable, honest and complete medical service on a health insurance basis, we shall have done them a service and helped to protect them, as well as ourselves, against what is fast becoming a racket.

PROGRAM OF INDIGENT CHILD CARE IN TEXAS

The Texas Department of Public Welfare, before entering on the program of aid to indigent children, conferred with the Council of Medical Economics of the State Medical Association of Texas. After frequent conferences and correspondence, the following agreement as to the medical services involved was drawn up and accepted by both parties:

This plan for securing medical examinations of parents claiming physical or mental incapacity under the Aid to Dependent Children Program constitutes an agreement made by and between the Texas State Department of Public Welfare and the State Medical Association of Texas and is predicated on the following statement of facts:

The Forty-Seventh State Legislature, acting under the authority of a constitutional amendment, appropriated \$1,500,000 to use for aid to dependent children. The legislature also made provision for participation in federal funds made available through the Social Security Act for aid to dependent children, which means that Texas can receive \$1,500,000 in federal funds for this program. In other words, the State Department of Public Welfare is now responsible for the administration of \$3,000,000 per year to be used in paying grants to dependent children who meet certain eligibility requirements.

The constitution of Texas, article III, section 51d, restricts payments of state funds to \$8 per month for one child in an eligible family. If there are two or more children in one home, the grant from state funds is limited to \$12 per month. This means that out of a total federal-state expenditure of \$3,000,000, including \$150,000 for administrative cost, one child may not receive a grant in excess of \$16 per month. If there is more than one child in an eligible family, the maximum grant allowable per family for federal-state funds is \$24 per month.

To participate in the Aid to Dependent Children Program, the child must meet definite eligibility requirements. He must be under 14 years of age, a citizen of the United States, a resident of Texas, and be deprived of parental support or care by reason of death of parent, continued absence from home or physical or mental incapacity.

The parent of every child claiming eligibility on the basis of physical or mental incapacity must have a medical examination to determine the presence and extent of incapacity. The parent must also be reexamined from time to time to establish continuing eligibility. As already pointed out, administrative funds are limited to \$150,000 per year (5 per cent). The administrative fund must be used to pay salaries and travel of the investigators, clerical assistance, postage, physical and mental examinations, and so on.

The department will pay \$3 for routine physical or mental examinations, and the same fee (\$3) will be allowed for each routine reexamination. The routine examination must include an examination of the entire body, a urinalysis, blood pressure, temperature and pulse rate. Only physicians who are legally licensed to practice medicine in Texas will be used, and the parent will have the choice of selecting from among these. Appropriate examination forms will be furnished by the State Department of Public Welfare, and the examination fee will be paid directly to the physician.

The department realizes that in rare cases it may not be possible to determine physical or mental incapacity without more complete laboratory work, x-ray and consultation with a specialist. For these few cases the examining physician is requested to write an individual letter to the State Department of Public Welfare, Austin, Texas, setting forth in detail the amount of laboratory test, x-ray and consultation services required. The department will then work out, on an individual case basis, with the examining physician, fees to be paid for the required services in line with those received in private practice for similar services from persons in average financial condition in the community in which the examining physician resides.

OFFICIAL NOTES

ADDRESSES BY THE PRESIDENT-ELECT

Dr. Fred W. Rankin, President-Elect of the American Medical Association, has been scheduled to deliver the following addresses during January:

January 16-17.—Visiting Surgeons' Club, Cleveland.

January 21.—Bronx County Medical Society, New York.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Refresher Courses.—The University of California Medical School will offer a refresher course on "Clinical Aspects of New Therapy" in Toland Hall, University of California Hospital, San Francisco, January 5-7. Designed to meet the needs of practicing physicians, the course will include the following subjects: sulfonamide drugs, drugs used on the central nervous system, organotherapy, and drugs used in treatment of diseases of the adrenal glands; new drugs acting on the heart and circulation, and clinical aspects of nutrition. Members of the faculty will participate. Complete programs may be obtained from the Dean's Office, University of California Medical School, San Francisco.

Effects of Different Lunches on School Children.—The state defense nutrition committee, the department of public health and the University of California Medical School, San Francisco, are cooperating in a two year nutrition study among school children in Santa Barbara County, to begin early this year. The study will be made by evaluating the effects of different types of lunches on the nutritional status of children in a representative section of Santa Barbara County. Three groups of two hundred children each will receive three different types of lunch. One group will eat lunches they are accustomed to bring from home. A second group will eat a scientifically balanced lunch prepared at school, and the third group will eat lunches from home but will be given a supplementary pellet supercharged with vitamins and minerals. The nutritional status of all the children will be checked before the study begins; vitamin and mineral reserves will be measured. Medical examinations of the children will be made at regular intervals, and a final survey will be made of the results of the program.

GEORGIA

Society News.—Dr. Cyrus W. Strickler Sr., Atlanta, addressed the Muscogee County Medical Society recently in Columbus on "Development of Treatment Methods in the Management of the Pneumonias."—The Georgia Urological Association was addressed, October 9, among others, by Drs. William F. Reavis and Lovick W. Pierce, Waycross, on "Renal Calculi."

Hospital News.—A federal grant of \$160,000 has been given to the Phoebe Putney Memorial Hospital, Albany, to provide construction and equipment of a new hospital and alterations. Existing facilities are inadequate at the hospital on account of increased defense activities at Turner Field, Darr Aero Tech Flying School and in the nearby towns of Bainbridge, Moultrie, Valdosta and Americus.

Annual Pediatric Meeting.—The Georgia Pediatric Society convened in annual session at the Biltmore Hotel, December 11. The speakers included:

Dr. Albert B. Sabin, Cincinnati, Epidemiology of Poliomyelitis.
Dr. Philip F. Barbour, Louisville, Ky., Active and Passive Immunization of Tetanus.
Dr. George M. Lyon, Huntington, W. Va., Sulfaguanidine Treatment of Bacillary Dysentery.

At an evening session Dr. Lyon discussed "Chemotherapy of Meningitis"; Dr. Barbour, "Rehabilitation of Poliomyelitis Patients," and Dr. Sabin, "Pathology, Symptomatology and Treatment of Poliomyelitis."

ILLINOIS

Precommitment Services for Mental Patients.—At a recent meeting of the managing officers of the mental institutions in Jacksonville, a plan of precommitment consultation service was adopted to be available to judges, physicians, relatives of patients, private and public welfare agencies and other professional groups. The service consists of an examination and an evaluation of a mental patient for whom admission to a state mental hospital is planned, to determine whether such institutionalization is needed and whether a more satisfactory plan can be worked out for the patient within his own community. The precommitment service will be limited to a single diagnostic interview, after which recommendations will be given the relatives, judge, physicians and other referring individual

or organization. It will be offered both at the hospital itself and also on a regular monthly basis in several centers of population in the counties the hospital serves, according to the *Welfare Bulletin*.

Chicago

Courses in Obstetrics.—Five postgraduate courses in obstetrics, each of four weeks' duration, will be offered at the Chicago Lying-In Hospital between January 12 and June 6, under the sponsorship of the state department of health and the Children's Bureau, U. S. Department of Labor. Features of the program consist of observations on current managements of normal and abnormal states of the pregnant, parturient and puerperal patient. There will be lectures, demonstrations, clinics and other teaching means to augment the operating room and birth room observations, and ward round discourses. The courses will be run on a nonprofit basis. A deposit of \$25 is required on registration, \$10 of which will be refunded at the completion of the course. Additional information and application blanks may be obtained by request from the Postgraduate Course, Department of Obstetrics and Gynecology, 5848 Drexel Avenue.

MARYLAND

Mosquito Control Program.—The state department of health has set up a mosquito control program in Maryland to control mosquito breeding in defense areas, primarily in the vicinity of the Aberdeen Proving Ground, the Edgewood Arsenal, the Bethlehem Steel Company, the Glenn L. Martin Company, Camp Holabird and the U. S. Naval Powder Factory at Indian Head. The work will consist of the application of oil to sluggish streams, small ponds and stagnant pools, the clearing of underbrush adjacent thereto and the draining of salt marshes where necessary. The project will be under the direction of a sanitary engineer detailed by the U. S. Public Health Service and the state bureau of sanitary engineering. The WPA has allocated \$42,000 to Maryland for the program and furnished all labor.

MASSACHUSETTS

Evans Memorial Lecture.—Dr. Alvah H. Gordon, Montreal, gave the first in the series of Robert Dawson Evans Memorial Lectures in Evans Auditorium, Boston, November 21. His subject was "Bone Changes in Certain Medical Diseases."

Personal.—Dr. John E. Gordon, Charles Wilder professor of medicine and epidemiology and head of the department, Harvard Medical School, and director of the American Red Cross-Harvard Hospital Unit in southwestern England, arrived in New York, November 10, on the Atlantic clipper. He came for a vacation and to recruit American staff members for the unit.

Society News.—Dr. John Romano, Boston, among others, addressed the Boston Society of Biologists, December 10, on "Psychiatric Manifestations of the Spontaneous Hypoglycemia."—The Massachusetts Society for Research in Psychiatry was addressed, December 9, by Saul Rosenzweig, Ph.D., and Dr. George E. Gardner, Boston, on "Sudden Death in the Anamnesis of Schizophrenia" and "Transient Psychotic Manifestations in Children."

Cancer Work at Harvard.—Harvard University and the Massachusetts General Hospital, Boston, have reached an agreement whereby the main phases of the work in cancer treatment and research now being carried on by the Collis P. Huntington Memorial Hospital of Harvard Medical School will be transferred to the general hospital. The step was taken because of the belief that the care and treatment of medical specialties can be more efficiently handled as part of a large institution of general scope than in smaller individual units. Under the new arrangement there will be transferred to the Massachusetts General Hospital the inpatient and outpatient services at the Huntington Memorial. The laboratory and research work now carried on by the Harvard Cancer Commission, established in 1899, will continue under the supervision of the commission. The research activities of Dr. Joseph C. Aub, associate professor of medicine at the Harvard Medical School, will be carried on at the general hospital in connection with the tumor clinic which the hospital has been conducting for many years. The remainder of the varied research work of the cancer commission will be continued in conjunction with the medical school. The equipment of the general hospital, including its 1,000,000 volt x-ray machine, will be available to all

patients at both the Huntington and the general hospital, and the Harvard supply of radium, heretofore used at the Huntington, will be available to the Massachusetts General Hospital. There will be no reduction in the number of beds for cancer patients in the community.

MICHIGAN

Society News.—The general practice section of the Wayne County Medical Society and the Detroit Pediatric Society were addressed, December 15, by Dr. Richard C. Eley, Boston, on "Nutritional Requirements of Infants and Children." Dr. Herrman L. Blumgart, Boston, will address a general meeting of the society, January 15, on "Coronary Collateral Circulation: Its Clinical and Pathological Significance."

Changes in Health Officers.—Dr. Frederick S. Leeder, Coldwater, director of the Branch County Health Department, has resigned to engage in research. Dr. Robert B. Harkness, Battle Creek, formerly director of the Barry County health unit, will serve as acting director of Branch County pending a permanent appointment.—Dr. Henry G. Steinmetz, Arlington, Va., is health commissioner of Genesee County during the absence of Dr. Leslie V. Burkett, Flint, who is taking postgraduate work in public health at Columbia University, New York.

Reelection of Examining Board.—The Michigan State Board of Registration in Medicine at its annual meeting in Lansing, October 14, reelected Drs. Elmer W. Schnoor, Grand Rapids, president; Claude R. Keyport, Grayling, vice president, and J. Earl McIntyre, Lansing, secretary. Attorney General Herbert J. Rushton appointed Mr. Milton G. Schanecupp, Owosso, special assistant attorney general, as legal counsel and investigating officer to the board. During the week previous to the board's meeting the governor reappointed Drs. Schnoor and Luther Peck, Plymouth, as members of the board and named Dr. Eugene S. Thornton, Muskegon, to succeed Dr. Garner M. Byington, Detroit; Dr. Harold L. Morris, Detroit, to succeed Dr. William C. Ellet, Benton Harbor, and Dr. Charles W. Balseur, Detroit, to succeed Dr. Francis B. Jarzembowski, Detroit. Dr. Morris and Dr. Thornton have previously served as members of the board.

MINNESOTA

Dr. Collier to Give Judd Lecture.—Dr. Frederick A. Collier, professor of surgery and chairman of the department of surgery, University of Michigan Medical School, Ann Arbor, will deliver the E. Starr Judd lecture at the University of Minnesota in the Chemistry Auditorium, Minneapolis, January 21. His subject will be "A Review of Studies on Water and Electrolyte Balance in Surgical Patients." The late Dr. Judd, an alumnus of the University of Minnesota Medical School, established this lectureship in surgery a few years before his death.

MISSOURI

Annual Hodgen Lecture.—Dr. Edwin P. Lehman, professor of surgery and gynecology at the University of Virginia Department of Medicine, Charlottesville, will deliver the annual Hodgen Lecture at the St. Louis Medical Society, January 13. His topic will be "The Use of Heparin."

Personal.—Dr. Evarts A. Graham, professor of surgery at Washington University Medical School, St. Louis, has been elected a member of the Royal Society of Sciences of Uppsala, Sweden, an organization founded in 1710. Dr. Graham was the only American among the five members of the society elected at this time. The election of membership is based on scientific merit. Dr. Graham is responsible for advances particularly in the fields of cholecystography and of chest surgery.—Dr. Hugh W. Maxey has been appointed surgeon and directing head of the Missouri State Penitentiary Hospital, Jefferson City, newspapers report.

NEBRASKA

District Meetings.—The Fourth Councilor District Medical Society devoted its recent meeting to a symposium on fractures sponsored by the Six County Medical Society. The speakers were Drs. William L. Sucha, Omaha, James W. Martin, Omaha, and Charles F. Ferriot, Lincoln.—The Seventh Councilor District Medical Society was addressed in Sutton recently by Drs. Joseph E. Uridil, Hastings, on "Infections of the Hand"; Raymond J. Wyrens, Omaha, on "Use of Sulfonamide Drugs in Internal Medicine," and Rolland Russell Best, Omaha, "Application of the Biliary Flush in Biliary Tract Disease."

NEW YORK

Distribution of Sulfadiazine for Pneumococcic Infections.—Sulfadiazine has recently been made available through the state department of health to registered doctors of medicine and hospitals in the state, exclusive of the city of New York, according to *Health News*. As with sulfapyridine and sulfathiazole, state issued sulfadiazine is intended only for those patients for whom purchase of this drug would be a hardship. The drug may be obtained in packages of sixty tablets of 0.5 Gm. each from laboratory supply stations. To comply with the ruling of the state board of pharmacy, the actual signature of physicians requesting sulfonamide drugs is required.

Personal.—Oscar Riddle, Ph.D., of the department of genetics of Carnegie Institution of Washington at Cold Spring Harbor, has been elected a foreign corresponding member of the Academia Nacional de Medicina, according to *Science*.—Dr. William H. Ross, Brentwood, first president of the Suffolk County Tuberculosis and Public Health Association, was presented with a citation for public service in recognition of his "farsighted leadership and unselfish service." The presentation was made on the occasion of the association's twenty-first anniversary in Patchogue recently.—Dr. John R. Ross, superintendent of the Harlem Valley State Hospital, Wingdale, was appointed head of the Hudson River State Hospital at Poughkeepsie, effective November 30, succeeding the late Dr. Ralph P. Folsom. Dr. Ross has been in the state hospital service since 1908.

Postgraduate Courses.—A postgraduate course on general medicine, arranged by Dr. Walter W. Palmer, New York, for the Westchester County Medical Society, will open at New York Hospital, Westchester division, White Plains, January 14, with a talk on "Nephritis" by Dr. Dana W. Atchley, associate professor of medicine, Columbia University College of Physicians and Surgeons. On March 11 asthma will be discussed by Dr. Albert VanderVeer, New York, and on May 13 rheumatic fever by Dr. Homer F. Swift of the Rockefeller Institute for Medical Research. A course on general medicine was given before the Rockland County Medical Society at the Summit Park Sanatorium, Pomona. Speakers, all of New York, included:

Dr. David D. Moore, Diabetes Mellitus, November 7.
Dr. Ralph G. Stillman, Significance of Laboratory Tests and Methods in the Practice of Medicine, November 14.
Dr. John D. Lytle, Nephritis, November 21.
Dr. Norman H. Plummer, Newer Chemotherapeutic Methods, November 28.
Dr. William B. Sherman, Asthma, December 5.
Dr. Leslie P. Barker, Syphilis, December 12.
Dr. Paul Reznikoff, Diagnosis and Treatment of Anemia, December 19.

New York City

Academy of Medicine Seeks Million Dollar Endowment.—The New York Academy of Medicine has launched a five year plan to obtain an endowment of "at least a million dollars" to insure an annual income sufficient to meet the requirements of continually enlarging services to the community, according to *New York Medical Week*.

Society Honors Ex-Presidents.—The first annual dinner to ex-presidents of the Medical Society of the County of Kings and the Academy of Medicine of Brooklyn will be held at the Hotel St. George, Brooklyn, January 17. Dr. Samuel J. Kopetzky, president of the state medical society, will present medals and scrolls, and speakers will be Hon. Fiorello H. LaGuardia, mayor of the city of New York, and Dr. Morris Fishbein, editor of THE JOURNAL. The Doctors' Orchestra will furnish the music.

Lectures for the Public.—The seventh series of lectures for the public on the army, art and romance of medicine, sponsored by the New York Academy of Medicine, opened on November 13 with the delivery of the Linsly R. Williams Memorial Lecture by Dr. James Alexander Miller, professor of clinical medicine, Columbia University College of Physicians and Surgeons. Dr. Miller's subject was "Tuberculosis: The Known and the Unknown." The second lecture was given by Dr. Tracy Jackson Putnam, professor of neurology and neurosurgery at Columbia, December 11, on "Mechanisms of the Mind." Other lectures in the series will be:

Dr. Abraham A. Brill, The Freudian Epoch (New York Academy of Medicine Anniversary Discourse), January 22.
Dr. Arnold L. Gesell, New Haven, Conn., Creative Behavior in Child and Adult, February 26.
Dr. Norman H. Jolliffe, History of Vitamin B, March 26.
Dr. Anton J. Carlson, Chicago, Newer Knowledge on Nutrition, April 23.

OHIO

Chief of Child Hygiene Division.—Dr. Susan P. Souther, formerly child hygiene physician in the bureau of child hygiene, Connecticut State Department of Health, Hartford, has been appointed chief of the division of child hygiene in the Ohio State Department of Health, Columbus.

Dr. Spies Wins Pharmaceutic Award.—The Award of Distinction of the American Pharmaceutical Manufacturers' Association was presented to Dr. Tom D. Spies, associate professor of medicine, University of Cincinnati College of Medicine, Cincinnati, during a meeting in Washington, D. C., December 8, in recognition of his work on nicotinic acid. The award is made annually to an investigator who, in the opinion of the committee, has made a fundamental contribution to public health in the field of drug therapy.

Society News.—Dr. Marion A. Blankenhorn, Cincinnati, discussed "Avitaminosis" before the Summit County Medical Society in Akron, December 2.—"Health in the Emergency" was discussed at a meeting of the Public Health Federation, Cincinnati, December 1, by Drs. Harry S. Sullivan, Washington, D. C., Arthur T. McCormack, Louisville, and John T. O'Rourke, D.D.S., Louisville.—Dr. Elmer L. Sevringhaus, Madison, Wis., discussed "Endocrine Treatment of Pituitary Disorders" before the Academy of Medicine of Cleveland, December 19. A tuberculosis committee has been formed by the academy to study the local tuberculosis setup and to make recommendations to the county commissioners; members of the committee are Drs. Joseph T. Wearn, Cleveland, chairman; Robert H. Browning, Warrenville; Raymond C. McKay, Edgar P. McNamee, Ulysses G. Mason Jr. and Charles F. Good, Cleveland.

Changes in the Faculty at Western Reserve.—Recent promotions on the faculty of Western Reserve University School of Medicine, Cleveland, include the following:

Dr. James R. Driver to associate clinical professor of dermatology and syphilology.

Donald E. Gregg, Ph.D., associate professor of physiology in the department of medicine.

Dr. Fred W. Dixon, assistant clinical professor of otolaryngology.

Dr. Curtis F. Garvin, assistant professor of medicine.

A. Sidney Harris, Ph.D., assistant professor of physiology

Dr. Joseph Seifter, assistant professor of pharmacology.

Dr. Reginald A. Shipley, assistant professor of medicine.

Dr. Charles T. Way, assistant clinical professor of medicine.

Dr. Clarence C. R. Jackson, assistant clinical professor of otolaryngology.

New appointments to the school include Ralph I. Dorfman, Ph.D., as assistant professor of biochemistry, assigned to the Brush Foundation.

OREGON

Changes in Health Officers.—Dr. Harry J. Anderson, Corvallis, has been named health officer of Benton County, succeeding Dr. William T. Johnson, who held the position for many years. The latter, who is retiring, also acted as health officer of Corvallis.—Dr. Clarence R. E. Lindgren, Eugene, has been appointed health officer of Lane County.

Society News.—Dr. William W. P. Holt, Medford, discussed "Pylorospasm" before the Jackson County Medical Society in Ashland, November 12.—Dr. Joe B. Davis, Portland, addressed the Marion-Polk Medical Society in Salem, November 18, on disorders of the foot.—Officers of the state medical association and the Mid-Columbia Medical Society met jointly at Hood River, November 17; Dr. William W. Baum, Salem, president of the state association, discussed activities of the society and Dr. Roger H. Keane, Portland, postgraduate educational opportunities.—The Umatilla County Medical Society devoted its meeting in Pendleton, November 12, to a panel discussion on sulfonamide compounds; the speakers were Dr. Norman A. David, professor of pharmacology, University of Oregon Medical School, Portland, and Dr. Joseph P. Brennan, Pendleton.—Dr. Stuart W. Harrington, Rochester, Minn., discussed "Diagnosis and Treatment of Carcinoma of the Breast" before the North Pacific Surgical Association, Portland, November 10.

VIRGINIA

Personal.—Dr. Warren T. Vaughan, Richmond, was awarded the honorary degree of master of science by the University of Michigan, Ann Arbor, October 4.—Dr. Clifford E. Waller, Silver Spring, Md., formerly medical director U. S. Public Health Service, has been appointed health officer of the newly organized health department in Loudoun County at Leesburg.

Grants at Medical College of Virginia.—Dr. Everett I. Evans, instructor in pharmacology and surgery, Medical College of Virginia, Richmond, has been given a grant of \$6,300 by the federal government, Office of Scientific Research Development, for further research on surgical shock, and Dr. John H. Scherer, assistant professor of medicine, Medical College of Virginia, Richmond, a grant of \$3,000 from the John and Mary R. Markle Foundation to continue his work in reticulocytosis in jaundice.

ALASKA

New Medical Society in Kodiak.—The Medical Society of Fort Greely, Kodiak, was organized at a meeting of physicians of the Naval Air Station and the adjoining army post, November 21. Nurses and enlisted personnel of the medical departments on Kodiak Island will be privileged to attend the monthly meetings. Lieut. Harry E. Balch, Kodiak, was chosen first president of the society. The organization meeting of the new group, called by Major Hiram S. Yellen, formerly of Buffalo, followed the opening of a new wing at the Fort Greely Station Hospital. Major Yellen is chief of the hospital.

GENERAL

Commonwealth Fund Aids China.—The Commonwealth Fund, New York, has made a grant of \$50,000 to the American Bureau for Medical Aid to China for the support of the Emergency Medical Service Training School in Kweiyang, China, according to *Science*.

National Social Hygiene Day.—The sixth National Social Hygiene Day will be observed throughout the country on February 4 with the theme "Keep America Strong, Help Build Better Health." Stress will be placed on the need for intensified action against syphilis and gonorrhea in industrial centers as well as military areas. Special attention will be directed toward the full realization of the menace of organized prostitution in areas adjacent to concentrations of armed forces and in industrial centers. Additional information concerning national and local programs may be received from the American Social Hygiene Association, Inc., 1790 Broadway, New York.

Annual Prize in Obstetrics.—The American Association of Obstetricians, Gynecologists and Abdominal Surgeons announces its annual "Foundation Prize." Three copies of all manuscripts and illustrations entered in a given year must be in hands of the secretary of the association before June 1. Manuscripts must be limited to five thousand words and be typewritten in double spacing on one side of the sheet. Illustrations should be limited to such as are required for a clear exposition of the thesis. A nom de plume must be used. The prize will be \$150, and those eligible to compete include interns, residents or graduate students in obstetrics, gynecology or abdominal surgery and physicians who are actively practicing or teaching obstetrics, gynecology or abdominal surgery. Dr. James R. Bloss, 418 Eleventh Street, Huntington, W. Va., is secretary of the association.

Nutrition Fellowship at Pittsburgh University.—The first of the fellowships in nutrition recently offered by Swift & Company, Chicago, will assist a study on the nature of fats and oils at the University of Pittsburgh, Pittsburgh. The work is under the direction of Charles G. King, Ph.D., professor of chemistry, University of Pittsburgh, and Herbert E. Longenecker, Ph.D., Buhl Foundation research fellow and assistant professor of chemistry. Dr. King, who received his degree at University of Pittsburgh in 1923, is known for his discovery of the chemical identity of vitamin C. Karl F. Mattil, Ph.D., has been appointed research fellow under the Swift grant. All projects to be eligible for the new Swift grants should be aimed at development of fundamental information on the nutritive properties of foods or the application of such information to the improvement of American diet and health.

Vitamin Research Wins Chandler Medal.—Robert R. Williams, D.Sc., chemical director of the Bell Telephone Laboratories of New York, and Roger J. Williams, Ph.D., professor of chemistry, University of Texas, Austin, have been awarded the Charles Frederick Chandler Medal of Columbia University for their work in vitamin chemistry. The former was named for his work on vitamin B₁ and the latter for his discovery of pantothenic acid and for contributions to the knowledge of the vitamin B complex. In commenting on the prize the New York Times states that this is the first time since the establishment of the award in 1910 that two persons have been named as recipients. The prize is a gold medal awarded annually to the person appointed Chandler lecturer under the Charles Frederick Chandler Foundation established by alumni and former students of Professor Chandler.

Committee on Industrial Ophthalmology.—The Section on Ophthalmology of the American Medical Association and the American Academy of Ophthalmology and Otolaryngology have appointed a joint committee on industrial ophthalmology to engage in appraisals of industrial visual testing technics, instrumentation, interpretation of results, and to promote programs of education among workers, employers, the medical profession and others. Members of the committee representing the Section on Ophthalmology are Drs. Albert C. Snell, Rochester, N. Y., chairman; Arthur M. Culler, Dayton, Ohio, and Hedwig S. Kuhn, secretary, Hammond, Ind. Members for the academy are Drs. Thomas D. Allen, Chicago; Edwin B. Dunphy, Boston, and John B. Hitz, Milwaukee. Working and advisory relationships have been developed between the new committee and the Council on Industrial Health of the American Medical Association.

Dr. Hume to Head China Famine Relief.—Dr. Edward H. Hume, New York, director of the Christian Medical Council for Overseas Work and former president of the Colleges of Yale-in-China, has been made chairman of the China Famine Relief U. S. A. Inc. founded in 1928. Since 1938 the organization has been sending funds to the war stricken country through the Church Committee for China Relief, which it formed in conjunction with the Federal Council of the Churches of Christ in America and the Foreign Mission Conference of North America. The Church Committee is a member agency of United China Relief. Dr. Hume was born in India of American parents. He graduated at Johns Hopkins University School of Medicine, Baltimore, in 1901. From 1905 to 1927 he was associated with the Colleges of Yale-in-China at Changsha, serving as president from 1923 to 1927. Returning to America, he became executive vice president of the New York Post-Graduate Medical School and Hospital, a position he held until 1933. He became director of the Christian Medical Council for Overseas Work in 1938.

War Conditions and Tuberculosis.—War conditions and the lengthened hours of work in defense industries have reversed the downward trend of tuberculosis, the New York *Times* stated, November 29, in commenting on a survey in the United States and abroad made by Godias J. Drolet, assistant director and statistician of the New York Tuberculosis and Health Association. The survey shows that already a decided increase in tuberculosis mortality is taking place in Europe. Although in the United States generally there has been no sharp change in the rate of this disease, danger signals are appearing, it was stated. In forty-six large American cities surveyed, nineteen showed a rise in tuberculosis mortality during the period from January 1 to November 15. For the entire nation the death rate was 45.9 per hundred thousand of population against 47.1 the year before. In the large cities, however, the death rate was 26 per cent above that of the nation at large. San Antonio had the highest rate, 144 per hundred thousand of population, while St. Paul, with only twenty-eight deaths, had the lowest. The rate in the five cities with more than one million population was for Philadelphia 65, Chicago 61, New York 54, Detroit 51 and Los Angeles 50. Mr. Drolet, who made a tuberculosis survey for the Rockefeller Foundation during the World War, pointed out that with increased activity and overtime work it is urgent that there be a corresponding increase in our vigilance against tuberculosis.

Tracing Source of Typhoid Outbreak.—An outbreak of typhoid in England was recently traced to a carrier, according to a report of Dr. John E. Gordon, director of the American Red Cross-Harvard Field Hospital in England. On September 4 and 9 two small boys living within 75 feet of each other were admitted to the Chippenham Isolation Hospital with a diagnosis of typhoid. On September 15 the Harvard unit was asked to investigate. A search for typhoid carriers and Vidal reactions was made in every member of both families and in the families of three food merchants in the vicinity common to the two families. No infected person was discovered. Other possible sources such as milk, drinking water, vegetable grocers and places visited were eliminated. On October 3 the two children had recovered so that they could converse and admitted having a common playmate, although they did not play with each other. A visit to the home of the third child revealed that the three children frequently played in the river, actually a small creek flowing within 30 feet of the home of this last child. This proved to be the site of a broken sewer which

often overflowed and which had overflowed during the critical incubation period of the two infected children. No case of the disease had been reported in the community for ten years. Subsequent testing disclosed the mother of the third child to be a typhoid carrier and one of a new group of evacuees in the village. It was believed that the children exchanged cookies or bread and butter and that the disease spread through the food prepared by the carrier for her child. The laboratory tests showed that the carrier strain of the mother was phage type A, which was the strain found in the two sick children.

CANADA

Faculty Changes at McGill.—Dr. Theodore R. Waugh, assistant professor of pathology, McGill University Faculty of Medicine, Montreal, has been made associate professor of pathology, and Dr. William L. Ritchie was promoted to be associate professor of radiology and head of the department. Dr. Carleton B. Peirce, director, department of radiology and radiologist in chief at the Royal Victoria Hospital, was made associate professor of radiology.

Lectures for General Practitioners.—The Academy of Medicine of Toronto announces a special course of lectures for the general practitioner, January 5-9. The program will include the following:

- Dr. Percy A. Sarjeant, The Hazard of Air Raids, January 5.
- Dr. John Harold Couch, Personal Protection in Air Raids, January 5.
- Dr. Robert W. Wesley, Significance of Uterine Bleeding from Non-malignant Causes, January 6.
- Dr. Nicholas D'Arcy Frawley, Management of Toxemia of Pregnancy, January 6.
- Dr. Hamnett A. Dixon, Diagnosis and Treatment of Common Skin Lesions, January 8.
- Dr. Ross A. Jamieson, Heart Disease in General Practice, January 8.
- Dr. Frank Burns Plewes, Treatment of Hemorrhoids and Varicose Veins, January 9.
- Dr. Charles R. B. Crompton, Significance and Danger of Painless Hematuria, January 9.

There will be a panel discussion on the sulfonamide derivatives, January 7, by Drs. Wilbert Hurst Brown, Philip H. Greey, Wilfred K. Welsh, James L. McCollum and Leslie Nelles Silverthorne. All are from Toronto.

LATIN AMERICA

Brazilian Quarterly Becomes Official Journal for Ophthalmologic Congress.—*Ophthalmologica Ibero-Americana*, the Brazilian quarterly abstract journal, is now the official organ of the Pan American Congress of Ophthalmology. *Ophthalmologica* has appeared only in Portuguese, but after January 1 all abstracts will be printed in Spanish and English or in Portuguese and English. Original articles, reports of scientific activities of the congress, news items and so on will be reproduced in all three languages. Dr. Moacyr E. Alvaro, São Paulo, Brazil, is managing editor, and the committee on literary exchange of the congress, consisting of all the ophthalmic editors of the Western Hemisphere under the chairmanship of Dr. J. Lyó Pavia, Buenos Aires, Argentina, forms the editorial board. *Ophthalmologica Ibero-Americana* will be sent without charge to all members of the Pan American Congress of Ophthalmology who shall have paid dues in advance. An annual membership fee of \$5 will be sufficient to supply the journal to all members and to finance the second Pan American Congress of Ophthalmology, which is to be held in Montevideo in November 1943. Interested ophthalmologists are asked to send their name and address together with the membership fee of \$5 to Dr. Conrad Berens, secretary-treasurer of the Pan American Congress of Ophthalmology, 411 First Avenue, New York.

FOREIGN

Paderewski Hospital Opened.—The Paderewski Hospital at Edinburgh, Scotland, has been opened, newspapers reported, December 7. The hospital has been established in connection with a medical school as part of the Polish Medical Center, Edinburgh, which has been in operation since March. A memorial to the late Ignace Jan Paderewski, pianist and Polish premier, the hospital will be open to Polish civilian refugees, to Polish soldiers in Scotland and, in an emergency, to the British public. The city of Edinburgh gave the building, and funds from the Paderewski Testimonial Fund in America have assisted in the expenses. The fund was started before Paderewski's death as a tribute on the occasion of the fiftieth anniversary of his American debut. Newspapers stated that, once Poland is free, the hospital will be transferred there.

The Mass Psychology Which Menaces the World

When Wilfred Trotter died in 1939 he was regarded as our greatest surgeon. But he had another title to fame; he was a philosopher. In 1908-1909 he contributed to the *Sociological Review* two essays on herd instinct, in which he questioned the accepted distinction between sociology and psychology. He argued that, as man was unknown as a solitary animal, every one must present the characteristics of a social animal or herd. He first dealt with instinct, which he defined as "inherited modes of reaction to bodily need or external stimulus." He distinguished three primary instincts: self preservation, nutrition and sex. But in gregarious animals, including man, he found a fourth instinct which modified and controlled these primary instincts. This he called the herd instinct. It was of three types: the aggressive, shown in the wolf and dog, the protective, shown in the sheep and deer, and the socialized, shown in the bee and ant. In the last the individual is completely absorbed into the major unit. Trotter held that the socialized type was the goal of man's development. Toward it his constantly growing altruism was directed. He expanded his essays into a famous book, which he published in 1916, entitled "Instincts of the Herd in Peace and War." As the extension of the original title shows, much that he wrote was inspired by the great war, then in progress. He gave to herd instinct a new importance in human psychology. He found in it the source of the individual's "opinions, credulities, disbeliefs and weaknesses." He wrote "Each one of us in his opinions, conduct, dress, amusement, religion and politics is compelled to be one of a class—the herd within the herd." Modern nations conformed to the herd types of the lower animals. Germany was "a perfect copy" of the wolf pack. "I am not intending to use a vague analogy," he said, "when I compare German society to the wolf, but to call attention to a real and gross identity. The psychic necessity which makes the wolf brave in a massed attack makes the German brave in a massed attack; the psychic necessity which makes the dog submit to his master's whip and profit by it makes the German submit to the lash of his officer and profit by it. . . . Such a people have no conception of the benign use of power but must regard war as an end in itself and peace as a somewhat irksome preparation for war."

All this was written in Trotter's book published twenty-five years ago. Today the *Times* gives, in its series of quotations under the caption "Old and True," the following extract from the book: "I admit to myself, quite frankly, my innermost conviction that the destruction of the German Empire is an indispensable preliminary to the making of a civilization tolerable by rational beings." This warning had no effect on our politicians, who would never dream that a surgeon, however eminent, or a philosopher, however acute, could provide any instruction of practical value on a political subject. A similar warning of the German peril given by a few public men, who included another philosopher, Frederick Harrison, the positivist, was ignored before the last great war. But now, as then, our enemies will find that they have made a mistake in relying on our normal aversion to militarism. If such warnings had been taken to heart how much suffering the world would have been saved! Trotter was by no means the only one among our public men who foresaw the danger, but no one dealt with it so scientifically and showed that it necessarily arose from the mass psychology of the Germans.

Is Alcohol in Any Sense a Food?

To a manual of scientific temperance teaching for the use of teachers and students, published by the Temperance Collegiate Association, Sir Frederick Gowland Hopkins, F.R.S., has contributed an essay on the relation of alcoholic beverages to nutrition. It is generally taught that as alcohol undergoes combustion in the body it acts as food. But Hopkins gives strong reasons for doubting this. Unlike our indispensable foods, alcohol disappears from the body in a few hours and cannot be stored. Its oxidation does not prove that it fulfils the functions of a food. Many deleterious substances are oxidized in the body and then eliminated. The energy liberated by the combustion of alcohol may well be unavailable for the support of any bodily function. Modern studies of the chemical events involved in muscular contraction give good reasons for doubting that alcohol can play a significant part in them.

These a priori considerations are supported by recent direct experiments which show that during work the oxidation of alcohol taken proceeds no faster than when the individual is completely at rest. Therefore the alcohol cannot have supplied energy for the work. In two young men whose diet and activities were carefully controlled, the rate of disappearance of alcohol from the body was studied for some hours when they were completely at rest. This rate was essentially the same on different occasions. Then the rate of disappearance was followed during bicycle riding, slowly for long periods or fast for shorter ones. The work did not increase the rate of disappearance of alcohol. It therefore could not have provided energy for the work done. The same result was obtained when the work was walking 20 miles over stiff country and in experiments on animals. The constancy of rate of combustion seems to be a device for protection rather than for utilization.

Even when no muscular work is done, heat derived from the combustion of food is necessary for maintaining the temperature of the body and the work of the internal organs. When the body is exposed to a low external temperature, combustion must increase to replace the heat lost through the skin. Can the combustion of alcohol supply any of this? Again, it was found that the combustion of alcohol was not quickened and so cannot meet the demand for greater heat production. Moreover, the dilating action on the cutaneous blood vessels increases the loss of heat. Therefore alcohol cannot protect against cold. Yet these two needs are just those which our non-nitrogenous foods characteristically supply. To suppose that alcohol can contribute in any direct sense to tissue growth would be absurd.

Insurance to Meet Hospital Bills

To encourage the formation of mutual insurance schemes which will assist the middle and professional classes to meet expenditure necessitated by illness necessitating specialist or surgical treatment undertaken in hospital pay beds or nursing homes, Lord Nuffield, famous for his munificent gifts to hospitals and medical education, has created a provident guaranty fund of \$750,000. This will be available for the purpose of guaranteeing the financial solvency of provident schemes. A condition is that the schemes shall be approved by the trustees of the fund and provide substantial cover for subscribers and members of their families on a contributory basis. Lord Nuffield's fund is available for areas outside London. In the London area King Edward's Hospital Fund has appointed a committee, under the chairmanship of Sir Bernard Docker, to sponsor a provident scheme to cater for the requirements of the middle and professional classes.

The Supply of Milk to School Children

More than 2,700,000 children obtain milk regularly in the public elementary schools. Nearly 600,000 are served twice daily with a third of a pint; the remainder get it once daily. Some 350,000 get the milk free; the rest pay 1 cent per third of a pint, which is only a third of the price paid by ordinary consumers at present. A demand that the scheme should be extended to other schools has been made, as the parents who prefer these schools are now paying as taxpayers for other people's children to have more milk than their own. The Ministry of Food would like to see the scheme extended, but financial considerations stand in the way. While the hardship is admitted, it is pointed out that the public elementary schools are open to all.

BUENOS AIRES

(From Our Regular Correspondent)

Sept. 15, 1941.

Center for Breast Milk in Buenos Aires

The Breast Milk Center of Buenos Aires is a public institute for the collection, storage and distribution of breast milk on a noncommercial basis. It has the same aims as have similar institutes in other countries and differs from the breast milk collecting depots which were established in Argentina about twenty years ago in that only the superfluous breast milk is collected; that is, the center is supplied not merely by wet-nurses. The women are periodically subjected to clinical, roentgenologic and serologic examination. The mother's own child is not deprived of milk as is sometimes the case in wetnurses. This institute is staffed with social workers, who keep in contact with the families of the donors as well as of the recipients and take interest also in problems of clothing and diet and if necessary secure financial and legal aid, hospitalization for mother and child, vaccination against smallpox and diphtheria and so on. The institute has demonstrated its value in the twelve years of its existence. In 1940 milk obtained from 346 women was distributed to 1,237 children. Of 5,300 liters collected during 1940 about 2,800 liters could be dispensed without charge. Depending on the economic conditions, the price per liter varies from nothing to 8 Argentine pesos (\$2.40).

Leprosy

According to E. M. Riveros, cases of leprosy have been observed in Colombia as follows: in 1936, 797 cases detected among 9,798 persons examined; in 1937, 834 among 31,279; in 1938, 767 among 31,268; in 1939, 654 among 55,633. The Asilo de Guadalupe, which admits healthy daughters of leprosy patients and has facilities for 250, was destroyed by fire in 1938 and its restoration has not been completed. San Bernardo can admit 400 children and 40 infants, another one 350 children and still another 100 children and 45 newborn infants. On May 1, 1940 these different institutes harbored 1,013 children. The state grants large subsidies to these institutions. The state has also had removed a large number of healthy children from the leprosariums; with financial support from the state they will remain under medical control up to the age of 15 years. From July 1938 to May 1940, 908 healthy children have been removed from the leprosariums; 532 were placed into the aforementioned asylums and 376 in families.

An analysis of the leprosy problem in the eastern provinces of Peru by M. H. Kuczynski-Godard and V. M. Pinedo demonstrates that the methods employed are inadequate. A well organized and medically well equipped rural colony is probably preferable to a hospital. In a first and cursory study of a district, 1.5 per cent of the population were found to have leprosy (44 cases).

According to Prof. V. Boettner (*Revista médica del Paraguay*, 1940) the state leprosarium of Paraguay at present has about

180 patients. Among the 140,000 patients admitted to the hospitals of Asunción from 1932 to 1936 there were 56 patients with leprosy. The number of leprosy patients in the army during the three year Chaco war was 78. The medical examination of the mobilized men during the war disclosed in all 187 cases of leprosy. Paraguay has no districts with a great concentration of leprosy. Boettner was able to detect 30 cases in his private practice.

The High Incidence of Circulatory Diseases

The Departamento Nacional de Higiene of Argentina reports a high incidence of cardiac and vascular diseases, which has been observed also in other countries. In Buenos Aires, for instance, with a population of 2.4 millions and a total mortality of 26,535, the fatalities from circulatory diseases were 26.9 per 10,000 inhabitants, or 23 per cent of the fatalities. These diseases are more frequent among men than among women, the ratio being 2 to 1; at the age level above 60 the ratio between the two sexes becomes equalized.

The report states further that in the United States the mortality from circulatory diseases is relatively lower than in Argentina and, in spite of this they present an economic burden of \$250,000,000, which is equivalent to 1,000 million Argentine pesos. The Departamento Nacional de Higiene estimates the burden for Argentina at 100 million Argentine pesos. The losses sustained by the pension fund owing to circulatory diseases go so far that of 514 persons who in 1940 wanted to take advantage of the pension funds 38.6 per cent intended to retire on account of circulatory diseases. The department attempts to remedy this problem by prophylactic measures. The large group of governmental employees is to be considered first. It has been suggested that, with the examination for tuberculosis, to which all governmental employees are to be subjected at five year intervals, an examination for circulatory diseases, especially for persons over 40, be combined. Persons in whom circulatory defects are discovered are, if possible, to be given other work more compatible with their state of health.

Personal

Guy Amerongen, a French industrialist who established a prize for the study of the interrelations between canned food and carcinogenesis but lost all of his possessions, is also seeking a new home in Argentina. The prize of 100,000 francs could not be distributed for twelve years. In 1939 the prize was awarded to Professor Roffo in recognition of a scientific contribution but was used by him to further the cultural relations between Argentina and France.

Dr. Mario Soto was appointed professor of pharmacology at the University of Buenos Aires. He will devote all his time to pharmacologic research and give up his clinical connections.

Prof. Aloysio de Castro, president of the academy of medicine in Rio de Janeiro and director of the general policlinic, has been given a doctorate honoris causa by the faculty of medicine in Buenos Aires.

Marriages

HASKELL WRIGHT FOX to Miss Ruby Lee, both of Greeneville, Tenn., in Asheville, N. C., Oct. 16, 1941.

ELDON EDGAR SMITH, Canton, Ohio, to Miss Patricia Matthews at Ludington, Mich., in October 1941.

PAUL D. ZUBRITZKY, McKees Rocks, Pa., to Miss Ilaria Sterniuk of Plymouth, Sept. 23, 1941.

FREDERICK H. BOWEN to Miss Henrietta Baldwin, both of Jacksonville, Fla., Oct. 25, 1941.

CLARENCE E. UMPHREY to Miss Helen Isabel Trimm, both of Detroit, Nov. 1, 1941.

JOSEPH CLEMENT FLYNN, Cincinnati, to Miss Deirdre Driver of Tampa, Fla., recently.

Deaths

Austin Smith McKittrick @ Elyria, Ohio; Eclectic Medical Institute, Cincinnati, 1888; University of Wooster Medical Department, Cleveland, 1902; fellow of the American College of Surgeons; past president of the Hardin County Medical Society and the Lorain County Medical Society; for many years member of the board of education of Kenton, Ohio; a founder of and surgeon to a hospital bearing his name; formerly trustee of the Ohio Northern University, Ada; aged 78; surgeon to the San Antonio Hospital, Kenton, and the Memorial Hospital, where he died, Nov. 3, 1941, of pneumonia.

Ellen Smith Stadtmuller, San Francisco; University of California Medical Department, San Francisco, 1912; member of the California Medical Association and the American Academy of Pediatrics; clinical instructor in pediatrics at his alma mater; chief of child hygiene, state department of public health; assistant chief, communicable disease department, Children's Hospital from 1918 to 1922; instructor and medical inspector, State Teachers College, from 1920 to 1922; member of the advisory committee of the National Society for the Prevention of Blindness; aged 58; died, Nov. 25, 1941.

Edwin Forrest Yancey, Sedalia, Mo.; Missouri Medical College, St. Louis, 1882; member and from 1910 to 1920 vice president of the Missouri State Medical Association; fellow of the American College of Surgeons; formerly medical director of the Missouri-Kansas-Texas Railroad Company; formerly chief of staff of the John H. Bothwell Memorial Hospital; aged 83; died, Nov. 21, 1941, of carcinoma of the prostate.

William Michael Mehl @ Buffalo; University of Buffalo School of Medicine, 1904; chairman of the New York State Commission for the Blind; consulting ophthalmologist for the state department of labor; on the staffs of the J. N. Adam Memorial Hospital, Perrysburg, and the Charitable Eye, Ear, Nose and Throat Hospital; aged 64; died, Nov. 28, 1941, in the Buffalo General Hospital.

Roy Thomas Rodaway, Roanoke, Ill.; Bennett Medical College, Chicago, 1913; member of the Illinois State Medical Society; past president of the Woodford County Medical Society; on the staff of St. Francis Hospital, Peoria; served during the World War; county coroner; aged 54; died, Nov. 4, 1941, at his summer home in South Haven, Mich., of coronary disease.

Francis LeRoy Phillips @ Assistant Surgeon, Lieutenant (junior grade) United States Navy, Mare Island, Calif.; University of Southern California School of Medicine, Los Angeles, 1936; entered the navy in August 1936; on the staff of the United States Naval Hospital; aged 32; died, Nov. 17, 1941, in the United States Naval Hospital, Brooklyn.

Theodore Henry Lemmerz, Jersey City, N. J.; New York Homeopathic Medical College and Hospital, New York, 1896; fellow of the American College of Surgeons; member of the Medical Society of New Jersey; ophthalmologist and director of clinics, Christ Hospital; aged 71; died, Nov. 8, 1941, of carcinoma of the rectum.

William Henry Marsh, Solomons, Md.; University of Maryland School of Medicine, Baltimore, 1876; member of the Medical and Chirurgical Faculty of Maryland; formerly associated with the U. S. Public Health Service; aged 90; died, Nov. 12, 1941, in the United States Marine Hospital, Baltimore, of carcinoma of the lung.

Thomas Douglass @ Ozark, Ark.; Missouri Medical College, St. Louis, 1889; president of the Tenth Councilor District Medical Society and secretary of the Franklin County Medical Society; for many years chairman for the Red Cross in Franklin County; aged 73; died, Nov. 7, 1941, in a hospital at Fort Smith.

Albert Clinton Leach, Orange, Mass.; Dartmouth Medical School, Hanover, N. H., 1894; member of the Massachusetts Medical Society; member of the local board of health for many years; aged 70; died, Nov. 9, 1941, in the Farren Memorial Hospital, Montague City, of cerebral hemorrhage.

William Herbert Mason @ Murray, Ky.; Vanderbilt University School of Medicine, Nashville, Tenn., 1899; past president of the Calloway County Medical Society; aged 66; medical director of a hospital bearing his name, where he died, Nov. 23, 1941, of Hodgkin's disease.

Ernest Maxwell Vardon, Los Angeles; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1898; member of the California Medical Association; on the

staff of the Queen of Angels Hospital; aged 71; died, Oct. 8, 1941, of retroperitoneal hemorrhage.

Douglas Hursh Vastine, Catawissa, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1923; member of the Medical Society of the State of Pennsylvania; aged 42; died, Nov. 14, 1941, in the Bloomsburg (Pa.) Hospital, of pneumonia and meningitis.

Robert Walker Hale, Thermopolis, Wyo.; Missouri Medical College, St. Louis, 1893; member of the Wyoming State Medical Society; formerly state senator and postmaster; at one time member of the state board of health; aged 72; died, Oct. 29, 1941.

Jim Hilliard Camp @ Pecos, Texas; University of Texas School of Medicine, Galveston, 1927; at one time instructor in anatomy at his alma mater; medical director of a hospital bearing his name; aged 39; was accidentally shot and killed, Nov. 16, 1941.

David Henry Davison, New York; College of Physicians and Surgeons, medical department of Columbia College, New York, 1876; member of the Medical Society of the State of New York; aged 87; died, Nov. 22, 1941, in the Mount Sinai Hospital.

William August Kriesel, Little Rock, Ark.; Minneapolis College of Physicians and Surgeons, 1897; member of the Arkansas Medical Society; served during the World War; on the staff of the Missouri Pacific Hospital; aged 71; died, Oct. 30, 1941.

Allen Johnson, San Antonio, Texas; Tulane University of Louisiana School of Medicine, New Orleans, 1916; member of the State Medical Association of Texas; served during the World War; aged 51; died, Oct. 13, 1941, of cerebral hemorrhage.

Mavity J. Spencer, Indianapolis; Central College of Physicians and Surgeons, Indianapolis, 1896; member of the Indiana State Medical Association; past president of the city board of health; formerly police surgeon; aged 70; died, Nov. 27, 1941, of coronary embolism.

Harry Thesdale Rosenthal, New York; University and Bellevue Hospital Medical College, New York, 1911; member of the Medical Society of the State of New York; on the staff of the Bronx Hospital; aged 54; died, Nov. 23, 1941, of coronary thrombosis.

Lloyd Henry Sarchet, Wellington, Kan.; State University of Iowa College of Homeopathic Medicine, Iowa City, 1898; member of the Kansas Medical Society; city and county health officer; aged 69; died, Nov. 14, 1941, in St. Luke's Hospital.

Edgar Burton Probasco @ Glens Falls, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1898; fellow of the American College of Surgeons; attending surgeon Glens Falls Hospital; aged 71; died, Nov. 5, 1941.

William S. Prather, Americus, Ga.; University of Georgia Medical Department, Augusta, 1889; member of the Medical Association of Georgia; formerly owner of the Americus Hospital; aged 73; died, Nov. 12, 1941, of coronary thrombosis.

Jesse Grim, Los Angeles; Western Pennsylvania Medical College, Pittsburgh, 1904; served during the World War; formerly passed assistant surgeon in the United States Public Health Service reserve; aged 64; died, Nov. 20, 1941.

Frank R. Smiley, Boonville, Mo.; Beaumont Hospital Medical College, St. Louis, 1888; member of the Missouri State Medical Association; was a member of the board of education and county coroner; aged 81; died in November 1941.

Leon Charles Lewis, Kansas City, Mo.; University Medical College of Kansas City, Mo., 1901; member of the Missouri State Medical Association; served during the Spanish-American and World wars; aged 65; died, Nov. 10, 1941.

Howe R. Coleman Sr., Colliertown, Va.; Medical College of Virginia, Richmond, 1898; chairman of the county board of health and formerly chairman of the county school board; aged 69; died, Nov. 7, 1941, of coronary thrombosis.

Clarence Atwood Rose, Ardmore, Pa.; Jefferson Medical College, Philadelphia, 1913; member of the Medical Society of the State of Pennsylvania; on the staff of the Bryn Mawr (Pa.) Hospital; aged 61; died, Nov. 13, 1941.

Edmund A. Terrell, Fredericks Hall, Va.; Medical College of Virginia, Richmond, 1885; member of the Medical Society of Virginia; for many years surgeon for the Chesapeake and Ohio Railway; aged 81; died, Nov. 18, 1941, of arteriosclerosis.

Mace Anderson Losee, Livingstonville, N. Y.; Cornell University Medical College, New York, 1902; member of the

Medical Society of the State of New York; for many years health officer; aged 63; died, Nov. 9, 1941.

Walker L. Stumbo, Lackey, Ky.; University of Louisville Medical Department, 1907; member of the Kentucky State Medical Association; county sheriff; formerly county judge; aged 58; died, Nov. 13, 1941, in Martin.

David J. Conyers, Halls, Tenn.; Memphis (Tenn.) Hospital Medical College, 1897; bank president; aged 76; died, Nov. 22, 1941, in the John Gaston Hospital, Memphis, of injuries received in an automobile accident.

Warren Lee Hall, Nicholls, Ga.; University of Georgia Medical Department, Augusta, 1913; member of the Medical Association of Georgia; served during the World War; aged 52; died in November 1941.

Alfred Martin Sutton, San Diego, Calif.; University of London Faculty of Medicine, London, England, and M.R.C.S., England, 1885; aged 82; died, Oct. 8, 1941, of fractured right femur and arteriosclerosis.

Eugene Le Roy Kellum, Richmond, Va.; University of Pennsylvania School of Medicine, Philadelphia, 1924; on the staff of the Gracc Hospital; aged 43; was killed, Nov. 15, 1941, in an automobile accident.

Earl Hudson Turner * Pampa, Texas; University of Texas School of Medicine, Galveston, 1934; aged 31; died, Oct. 12, 1941, as a result of injuries received in an accidental fall down an elevator shaft.

Baxter Rittenberry, Selma, Ala.; Birmingham Medical College, 1899; past president of the Dallas County Medical Society; aged 68; died, Nov. 19, 1941, of arteriosclerosis and cerebral hemorrhage.

Joseph Michel Arthur Valois, Montreal, Que., Canada; School of Medicine and Surgery of Montreal, Faculty of Medicine of the University of Laval at Montreal, 1900; aged 66; died, Nov. 16, 1941.

Mitchell Lawrence Moran, St. Petersburg, Fla.; Georgetown University School of Medicine, Washington, D. C., 1935; member of the Florida Medical Association; aged 31; died, Nov. 22, 1941.

Charles Henry Wilson, New Brighton, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1906; aged 69; died, Nov. 1, 1941, in the Beaver Valley Hospital of carcinoma of the stomach.

Harvy Nally, Cainsville, Mo.; University of Missouri School of Medicine, Columbia, 1876; member of the Missouri State Medical Association; aged 86; died, Nov. 3, 1941, of coronary thrombosis.

Eugene Leffler Gilmore, Tallapoosa, Ga.; Marion-Sims College of Medicine, St. Louis, 1892; member of the Medical Association of Georgia; aged 72; died, Nov. 16, 1941, of septicemia.

K. Arvid Enlind, New York; College of Physicians and Surgeons, Baltimore, 1893; served during the World War; aged 68; died, Nov. 17, 1941, in the Veterans Administration Facility.

Robert Graham Contrell, New York; University of Pennsylvania Department of Medicine, Philadelphia, 1896; aged 68; died, Nov. 26, 1941, in Englewood, N. J., of carcinoma of the prostate.

Arthur Horton Mann * Silver City, N. M.; University of Pennsylvania School of Medicine, Philadelphia, 1919; aged 48; died, Nov. 2, 1941, of lobar pneumonia and pulmonary tuberculosis.

James Stanley Gardner, Winnipeg, Man., Canada; University of Manitoba Faculty of Medicine, Winnipeg, 1923; aged 44; died, Nov. 25, 1941, of herpes zoster and pulmonary tuberculosis.

Calvin H. Maust, LeCompton, Kan.; Central Medical College of St. Joseph, Mo., 1905; member of the Kansas Medical Society; aged 65; died, Nov. 4, 1941, in a hospital at Topeka.

David H. Thornton, Princeton, W. Va.; College of Physicians and Surgeons, Baltimore, 1893; aged 76; died, Nov. 19, 1941, in Roanoke, Va., of coronary sclerosis and hypertension.

Paul Alexander Johnstone * Kansas City, Mo.; University Medical College of Kansas City, Mo., 1903; aged 75; died, Nov. 9, 1941, of coronary occlusion and pulmonary embolism.

Hartwell Blount Hyde, Nashville, Tenn.; Vanderbilt University School of Medicine, Nashville, 1878; aged 88; died, Nov. 12, 1941, in the Davidson County Hospital of senility.

John William Smart, Cottontown, Tenn.; University of Tennessee Medical Department, Nashville, 1886; aged 80; died, Nov. 16, 1941, in the Protestant Hospital at Nashville.

Joseph M. Hale, Dearborn, Mo.; Ensworth Medical College, St. Joseph, 1891; member of the Missouri State Medical Association; aged 77; died, Nov. 10, 1941, in Kansas City.

Lawrence Miles Gwinn * Denver; University of Colorado School of Medicine, Denver, 1913; on the staff of the Presbyterian Hospital; aged 53; died, Nov. 30, 1941.

Richard Churchill Travis * Indianapolis; University of Michigan Medical School, Ann Arbor, 1925; served during the World War; aged 42; hanged himself, Nov. 23, 1941.

John Dana Robbins, Mount Ida, Ark.; Memphis (Tenn.) Hospital Medical College, 1902; member of the Arkansas Medical Society; aged 68; died, Oct. 29, 1941.

Charles Henry Walter, Oakland, Calif.; Hahnemann Medical College and Hospital of Philadelphia, 1894; served during the World War; aged 74; died, Nov. 22, 1941.

Milton Elliott Cannon, Riceville, Tenn.; Lincoln Memorial University Medical Department, Knoxville, 1910; served during the World War; died, Nov. 28, 1941.

Charles J. Ross, Dover, Ark.; Memphis (Tenn.) Hospital Medical College, 1892; past president of the Pope County Medical Society; aged 74; died, Nov. 15, 1941.

George McGowan Stuart, Cupar, Sask., Canada; Manitoba Medical College, Winnipeg, Man., 1906; chairman of the public school board; aged 59; died, Oct. 28, 1941.

George Lewis Fuquay, Coats, N. C.; North Carolina Medical College, Charlotte, 1916; served during the World War; aged 49; died, Nov. 28, 1941.

Henry M. Kerzman, Detroit; Universität Bern Medizinische Fakultät, Switzerland, 1921; aged 53; died, Nov. 22, 1941, in the Harper Hospital.

Frederick David Brandenburg, La Farge, Wis.; Bellevue Hospital Medical College, New York, 1885; aged 79; died, Nov. 17, 1941, in La Crosse.

Joseph Thompson Graham, Draper, Va.; Medical College of Virginia, Richmond, 1923; aged 45; died, Nov. 29, 1941, in the Pulaski (Va.) Hospital.

John D. Wilson, Bowie, Texas; Memphis (Tenn.) Hospital Medical College, 1892; aged 78; died, Nov. 17, 1941, in the Bowie Clinic Hospital.

John Curtis Black, Bradenton, Fla.; University of Arkansas School of Medicine, Little Rock, 1911; aged 54; died, Nov. 26, 1941, in Corning, Ark.

John H. McCain * Arcola, Ill.; University of Louisville (Ky.) Medical Department, 1891; aged 72; died, Nov. 24, 1941, of cerebral hemorrhage.

Lilla B. Wood, Reed City, Mich.; Saginaw (Mich.) Valley Medical College, 1901; aged 74; died, Nov. 26, 1941, in the Reed City Hospital.

William G. Mullarky, Huntington, W. Va.; State University of Iowa College of Medicine, Iowa City, 1887; aged 83; died, Nov. 14, 1941.

Jack Sawyer Shipp, Anniston, Ala.; Louisiana State University School of Medicine, New Orleans, 1940; aged 35; died, Nov. 16, 1941.

Francis Conrad Vogt * Brooklyn; Long Island College Hospital, Brooklyn, 1900; aged 62; died, Nov. 19, 1941, of heart disease.

William Henry Hodges, Finger, Tenn.; University of Nashville Medical Department, 1898; aged 72; died, Nov. 16, 1941.

Theophile Hubert Wilson, Buffalo; Trinity Medical College, Toronto, Ont., Canada, 1900; aged 65; died, Nov. 30, 1941.

Robert Lee Justice, Haines City, Fla.; Medical College of Alabama, Mobile, 1894; aged 70; died in November, 1941.

J. Mills Boal, San Diego, Calif.; New York Homeopathic Medical College, New York, 1884; aged 85; died, Oct. 3, 1941.

Backus M. McIntyre, Winside, Neb.; John A. Creighton Medical College, Omaha, 1905; aged 70; died, Nov. 8, 1941.

William Riley Tanner, Lubbock, Texas (licensed in Texas, under the Act of 1907); aged 89; died, Nov. 13, 1941.

Charles Barber Ballard, Marietta, Ohio; Miami Medical College, Cincinnati, 1899; aged 80; died, Nov. 7, 1941.

Cyrus S. Keagy, Mill Shoals, Ill.; Missouri Medical College, St. Louis, 1889; aged 78; died, Nov. 19, 1941.

William A. Wilson, Detroit; Detroit College of Medicine, 1895; aged 71; died, Nov. 15, 1941.

Correspondence

PARALDEHYDE OR BENZYL ALCOHOL AS CAUSE OF FATALITY

To the Editor:—Since its introduction in obstetrics, paraldehyde has proved to be a valuable analgesic agent in labor. In addition to its excellent analgesic and amnesic properties, its usefulness has been greatly enhanced by the relaxation and sleep it affords the parturient patient between pains. Most physicians who have used this drug have been impressed with the wide margin of safety it enjoys over other commonly employed analgesics. In the hands of different obstetricians, and with varying technics of administration, it has been found to possess a high degree of safety for both mother and child. Hanson (*California & West. Med.* 47:191 [Sept.] 1937) has reported a case in which an overdose (120 cc.) of paraldehyde was given rectally during labor, with complete recovery of the mother and the delivery of a normal infant in good condition. Yet reports of 4 cases have appeared in the literature incriminating paraldehyde, either directly or indirectly, as the cause of maternal death. Paraldehyde may be exonerated at once in the first case, for three rectal instillations of formaldehyde were given by mistake instead of the intended paraldehyde medication (Kane, H. F.; Roth, G. B., and Mandy, T. E.: *Delaware State M. J.* 10:197 [Sept.] 1938).

Kotz, Roth and Ryon (*THE JOURNAL*, June 25, 1938, p. 2145) have attributed the death of their patient to an idiosyncrasy to paraldehyde. Although she became critically ill soon after receiving a single dose of 31 cc., death occurred only after cesarean section was performed. One may question, therefore, what the outcome might have been had a conservative course of treatment been followed.

Most recent is the report of Shoor (*THE JOURNAL*, Nov. 1, 1941, p. 1534). This author administered 12 cc. of paraldehyde and 6 cc. of benzyl alcohol to a primigravida aged 21 who had been in labor for about thirty-one hours. Three and one-half hours later she was found cyanotic and dyspneic and died following a generalized convulsion twenty-one and one-half hours after receiving the paraldehyde. The baby also died shortly after delivery, it too suffering generalized convulsions. Shoor, like Kotz, Roth and Ryon, attributed the maternal death to an idiosyncrasy to paraldehyde. It would appear unlikely that the fetus shared this "idiosyncrasy," but in view of both mother and child having undergone a similar mode of death a common cause of death seems reasonable. This, I believe, can be found in the benzyl alcohol. Used in conjunction with rectal instillations of paraldehyde, benzyl alcohol serves as a local surface anesthetic to the rectal mucosa. Kane and Roth (*THE JOURNAL*, Nov. 21, 1936, 107, p. 1710) have recommended a constant dose of 1.5 cc. When one of their patients was given, by mistake, 115 cc. of this drug, death ensued. Benzyl alcohol, which acts as a protein precipitant in the body, has been found lethal for mice, kittens and guinea pigs in doses of from 1 to 2 cc. per kilogram of body weight. When toxic amounts of this drug were injected into animals, convulsions often resulted (Macht, D. I.: *J. Pharmacol. & Exper. Therap.* 11:263 [April] 1918).

It is therefore submitted that Shoor's patient succumbed probably as a result of an excessive dose of benzyl alcohol, a substance of relatively high toxicity, rather than because of an idiosyncrasy to paraldehyde. Although reports of isolated cases exist in the literature, attributing fatal reactions to therapeutic doses of paraldehyde, there is no incontrovertible evidence that a single maternal death has ever resulted directly from the proper use of this valuable analgesic agent in obstetrics.

HAROLD SPEERT, M.D., St. Louis.

SUGGESTIONS FOR THE POSSIBLE CONTROL OF THE AMERICAN SUMMER ENCEPHALITIDES

To the Editor:—A recent editorial in *THE JOURNAL* (New Developments in Knowledge of Encephalitis, October 18, p. 136) reviews recent knowledge of certain "seasonal" encephalitides affecting man.

Since the outbreak in Paris, Ill., in 1932, epidemic summer encephalitis, epidemiologically not dissimilar to that occurring in the spring in Russia and to that of the late summer and autumn in Japan and Russia, has become increasingly important as a disease of man in the United States, Canada and Mexico. Approximately 3,000 cases were reported during the summer of 1941. At least three viruses may be responsible for the American outbreaks—that named for the St. Louis epidemic and those of the eastern and western types of equine encephalomyelitis. These three known American viruses are so closely related epidemiologically and clinically that the St. Louis infection should no longer be set apart from the so-called equine diseases either in name or in thought. For example, a large survey on serum neutralization made in the Yakima Valley, Washington, indicates that in this endemic area the western virus and the St. Louis virus infect, in approximately like proportions, horses and many other mammals and birds (Hammon, W. M.; Gray, J. A.; Evans, F. C.; Izumi, E. M., and Lundy, H. W.: *Western Equine and St. Louis Encephalitis Antibodies in the Sera of Mammals and Birds from an Endemic Area, Science* 94:305 [Sept. 26] 1941). Also intracerebral inoculation of horses with any of these viruses will produce encephalomyelitis (Cox, H. R.; Philip, C. B., and Kilpatrick, J. W.: *Susceptibility of Horses to St. Louis Encephalitis Virus, Pub. Health Rep.* 56:1391 [July 4] 1941). Furthermore, the same species of mosquitoes was found infected with both the St. Louis and the western equine viruses (Hammon, W. M.; Reeves, W. C.; Brookman, B.; Izumi, E. M., and Gjullin, C. M.: *Isolation of the Viruses of Western Equine and St. Louis Encephalitis from Culex Tarsalis Mosquitoes, Science* 94:328 [Oct. 3] 1941). Thus these three may be considered as one group in our discussion of general control measures.

Before the formulation and enforcement of control measures are seriously undertaken there should be a reasonably complete and well founded knowledge of the means of transmission and other important epidemiologic data. I shall briefly review the facts to see whether the profession has arrived at such a stage.

Mosquitoes were suspected as vectors of the eastern and western viruses, first on the basis of epidemiologic and then on laboratory evidence; both viruses have been repeatedly transmitted by *Aedes* mosquitoes in the laboratory (Davis, W. A.: *A Study of Birds and Mosquitoes as Hosts for the Virus of Eastern Encephalomyelitis, Am. J. Hyg.* 32:45, sec. C [Sept.] 1940). The St. Louis virus, at the time it was first recognized, was considered by one group of investigators to be spread by the respiratory tract (Leake, J. P.; Musson, E. K., and Choppe, H. D.: *Epidemiology of Epidemic Encephalitis, St. Louis Type, THE JOURNAL*, Sept. 8, 1934, p. 728) and by others as mosquito borne (Casey, A. E., and Broun, G. O.: *Epidemiology of St. Louis Encephalitis, Science* 88:450 [Nov. 11] 1938. (Lumsden, L. L.: Unpublished official report). Japanese workers reported laboratory transmission with *Culex pipiens* (Mitamura, T.; Yamada, S.; Hazato, H.; Mori, K.; Hosoi, T.; Kitaoka, M.; Watanabe, S.; Okubo, K., and Temjin, S.: *Ueber den Infektionsmodus der epidemischen Enzephalitis: Experimentelle Untersuchungen über ihre Ansteckung durch Mücken, Tr. Jap. Path. Soc.* 27:573, 1937), but in the United States this transmission has not been confirmed (Fulton, J. D.; Greutter, J. E.; Muether, R. O.; Hanss, E. B., and Broun, G. O.: *Observations Concerning Culex Pipiens as a Possible Carrier of St. Louis Encephalitis, Proc. Soc. Exper. Biol. & Med.*

44:255 [May] 1940). During the summer of 1941 in the Yakima Valley both the St. Louis and the western viruses were repeatedly isolated from *Culex tarsalis* (Hammon, W. M.; Reeves, W. C.; Brookman, B.; Izumi, E. M., and Gjullin, C. M., to be published). Thus insect transmission of all three types seems to be rather well established, though the final evidence of demonstrating the ability to transmit for the particular mosquito found naturally infected is still lacking.

The finding of western equine and of St. Louis virus in nasal washings of experimental horses by Records and Vawter (Equine Encephalomyelitis Cross Immunity in Horses Between Western and Eastern Strains of Virus, Supplemental Report, *J. Am. Vet. M. A.* 39:773, 1935) and by Cox, Philip and Kilpatrick respectively and the ease of intranasal infection in the laboratory especially of the latter disease (Vawter, L. R., and Records E.: Respiratory Infection in Equine Encephalomyelitis, *Science* 78:41 [July 14] 1933) makes it unwise to deny the possibility of this route of infection altogether. The importance of finding virus in the nasal washings of 1 horse from an experimentally induced St. Louis infection (Cox, Philip and Kilpatrick) should not be exaggerated, for in our experiments the virus was readily found in the blood stream in 2 horses during inapparent infections and could not be detected in the nasal washings (Hammon, W. M.; Carle, B. N.; Izumi, E. M., and Britton, J. W.: St. Louis Encephalitis in the Horse, to be published). Thus accumulated epidemiologic and laboratory evidence points strongly to the greater importance of transmission by insects.

Conclusive evidence now indicates that these viruses are widespread in smaller animals, the eastern type having been isolated from three species of birds and the western type from a prairie chicken (Cox, H. R.; Jellison, W. L., and Hughes, L. E.: Isolation of Western Equine Encephalomyelitis Virus from a Naturally Infected Prairie Chicken, *Pub. Health Rep.* 56:1905 [Sept. 26] 1941). Preliminary tabulation of results of neutralization tests on about 300 serums from mammals and birds in the Yakima Valley, Washington (Hammon, Gray, Evans, Izumi and Lundy), now controlled by a series of about 150 bloods from non-encephalitis areas, indicates that approximately 50 per cent of all domestic animals from this endemic area as well as about 12 per cent of the sampled members of wild species are infected at some time with both the St. Louis and the western virus (Hammon, Gray, Evans, Izumi and Lundy). This widespread infection occurs in most instances without any apparent epizootic except in horses.

Reports of the disease in horses and man, frequent instances of the isolation of the viruses and serologic tests give data of a useful nature regarding the geographic distribution of the infections and suggest that new areas are being involved each year and that the disease is reappearing in areas apparently free from it for long periods of time. The western virus has now been reported from every state west of the Mississippi River and from about three fourths of all counties within these states, as well as in numerous areas east of this line. Mass vaccination of horses, though partly responsible for fewer total cases in this species since 1938, has not checked the apparent spread. Since knowledge of the St. Louis virus has until now been limited to its recognition in human beings, less is known of its distribution, but such evidence as is available suggests that it is present in many areas of both the East and the West. The eastern infection appeared for a time to be limited to the area east of the Appalachian Mountains but in 1940 was found in Alabama and in 1941 in several parts of Texas. In the Rio Grande Valley during the summer of 1941 I obtained serologic evidence of both eastern and western virus infections in nonfatal cases in man and of all three types in horses.

With this knowledge of the means of transmission and of the apparent spread and distribution, it would seem that physicians

are now ready to face the important problem of what they can and will do about it. The large irrigated areas of certain Western states are known to offer ideal conditions for annual epidemics. The eastern type virus is by far the most dangerous to horse and man and seems to be rapidly moving westward and may appear next year or the year after in the great San Joaquin and Sacramento valleys of California and in other similar areas, where it can be expected to become endemic. Can it be prevented from doing so? Can it be prevented from entering the Dakotas and the great Northwest, including portions of Canada? Can it be prevented from recurring in Massachusetts and other eastern areas? In areas of the Western and Central states in which the western virus is now firmly established, can the disease be controlled? Can the three viruses now present in Texas on the Gulf Coast and the lower Rio Grande Valley, first observed in man in 1941, be prevented from causing epidemics in the large concentrations of Army and Navy personnel located in these areas?

I shall consider the more probable means of spread from one area to another: 1. The shipment of domestic animals just after natural infection could result in mosquito infection at any point at which these animals might be delivered from one to six days after shipment, given the vector and other suitable environmental conditions. This is evident from the fact that inoculation of birds and small mammals in the laboratory by the subcutaneous or intracutaneous route (similar to insect inoculation) or by intracerebral inoculation results in the virus circulating in the blood during some period from twelve to ninety-six hours after inoculation (Ten Broeck, Carl: Birds as Possible Carriers of the Virus of Equine Encephalomyelitis, *Arch. Path.* 25:759 [May] 1938. Howitt, B. F.: Comparative Susceptibility of Wild and Domestic Birds and Animals to the Western Virus of Equine Encephalomyelitis (Br. Strain) in California, *J. Infect. Dis.* 67:177 [Nov.-Dec.] 1941. Davis). In horses it may appear as late as six days after inoculation (Records and Vawter). 2. Given an infected mosquito, the possibility of its transportation by airplane, train, automobile or boat must be considered. 3. Migratory birds in an area such as the lower Rio Grande Valley, in which the infection occurs in horses as early as March, might become infected just before beginning flight northward and serve to infect mosquitoes at certain places where the birds temporarily rest.

To counteract these three possible methods of spread, the following might be considered: 1. A quarantine period for domestic animals shipped during the summer from known infected areas. This should be of about four days for small and six days for large animals and would have to be in mosquito protected quarters. There is no evidence at present to indicate a prolonged carrier state in any except an arthropod host, so there is no justification for a prolonged quarantine period. 2. Mosquito inspection and spraying are now practiced in yellow fever and malaria areas for air, water and land vehicles and could be applied to encephalitis areas. California already has entomologic inspection stations at important points of entry to the state, and these agricultural protective measures might be extended to protect man and horses from the highly fatal eastern encephalomyelitis virus. 3. Migratory birds would still jeopardize the situation even if these other measures were put into effective practice. Outside of extermination of these, a thought that can be dismissed entirely, intense local control measures in infected areas, to be considered later, would reduce the likelihood of birds becoming infected in southern endemic regions.

Undoubtedly a carefully planned and well correlated program which envisions the problem as a national or international one, rather than one of states or counties alone, could change the natural course of events.

Not less important, and not unrelated, is the question of local control where one or more of these viruses is now established.

When one considers the vast extent of the reservoir and the difficulties involved in complete elimination of mosquitoes in irrigated areas, it is obvious that the problem is somewhat similar to that of sylvatic plague—to learn how best to live with it rather than how to eradicate it. The following possibilities are pointed out:

1. As soon as the particular arthropod vector or vectors of the region are incriminated, and immediate steps should be taken to do so, their control should be considered. In most instances at least partial control will be practicable. If *Culex tarsalis* is the vector, however, owing to its ability to breed under such varied conditions, its effective control in certain areas will be entirely impracticable. Careful screening of homes and avoidance of mosquito infected areas during the hours when they customarily bite will offer partial protection. Those persons who, because of occupation, cannot remain indoors at these hours should wear protective clothing and use repellants, of which reasonably satisfactory types are now available.

2. Vaccination of man is being practiced on a small scale at present and deserves careful evaluation. Vaccination of horses for both the eastern and the western virus has proved highly effective. It is practicable for these animals because the morbidity rate without vaccination is usually about 10 per cent and the fatality rates are from 30 to 90 per cent. If an occasional horse dies or suffers a severe reaction from vaccination, it is relatively unimportant. In man, however, morbidity rates in the reported outbreaks (reports incomplete for 1941) have ranged from less than 1 to a maximum of about 150 per hundred thousand for a county or up to 500 per hundred thousand for a smaller political subdivision. Mortality has varied from 3 to 30 per cent in the western and St. Louis outbreaks. Let us consider how many persons would require vaccination for each life saved in what is considered a severe and unusual outbreak. Had the outbreak in St. Louis County and City in 1933 (morbidity rate 100 per hundred thousand and case fatality rate 20 per cent) been predicted and a perfect vaccine been available, for each life saved 5,000 persons would have been vaccinated. In an area such as the Yakima Valley, where annual vaccination of the population might be considered, because the disease appears annually, over the last three years for each life saved 13,900 vaccinations would have been performed. Until the outbreak involving the Dakotas in 1941, the morbidity rates in this area have been higher than anywhere else in the United States. Since at least two viruses are present in the area, double vaccination would probably have been necessary. In the most heavily infected counties of the San Joaquin Valley of California, much greater numbers would require vaccination for each life one would expect to save. Moreover, in this area the migratory population most needing vaccination would present an extremely difficult administrative problem. Most epidemics, however, are not predictable and, when recognized and the virus or viruses responsible identified in the laboratory, the time for vaccination to be effective would probably have passed. Since man is an unimportant reservoir, vaccination of a part of a population would not appreciably decrease the chance of infection for the unvaccinated group, as it does in smallpox. Some untoward reactions can be expected in every few thousand vaccinations, including the possibility of death, as is the case with any vaccine now used on human beings and with these specific vaccines when used on horses. Thus it would seem premature to recommend general vaccination of man in epidemic or endemic areas and not advisable, unless morbidity rates increase greatly above those so far reported, to compare with those rates encountered in certain communities in Russia, where vaccination is practiced for their spring, tick-borne encephalitis. There, in one community in which there were unvaccinated controls, it appears that 1 life was saved for every group of 267 persons vaccinated. Selected groups of heavily exposed persons, prob-

ably on an occupational basis, such as certain laboratory workers or agricultural workers, might well be immunized. This is now being practiced for the eastern and western viruses with reasonably good evidence that it is effective (Beard, D.; Finkelstein, H., and Beard, J. W.: Repeated Vaccination of Man Against the Virus of Equine Encephalomyelitis, *J. Immunol.* 40:492 [April] 1941). However, vaccination must be repeated yearly. At present no vaccine is available for the St. Louis infection.

3. Zoning restrictions to eliminate domestic stock and fowls from cities, suburban areas and small towns would undoubtedly be an effective measure in reducing human morbidity rates and deserves serious and immediate consideration. The distribution of the human disease and the preponderance of infection in domestic animals present strong evidence pointing to close association of man with a concentrated population of domestic animals as an essential to a high morbidity rate. In large cities, where zoning regulations are now enforced, despite the large human population few cases occur, and these can usually be traced to exposure elsewhere (Hammon, W. M., and Howitt, B. F.: *Epidemiological Aspects of Encephalitis in the Yakima Valley, Washington: Mixed St. Louis and Western Equine Types*, *Am. J. Hyg.*, to be published). Such control measures, although they will result in certain hardships on persons engaged in raising poultry or keeping stock of any kind in residential districts, are practicable and would undoubtedly be highly effective.

4. Animals that would be difficult to eliminate, such as dogs, and all animals in areas in which owners of small tracts live under conditions closely simulating rural towns could probably be prevented from serving as reservoirs of virus by vaccination. Technics and vaccines would have to be developed, but this could be readily accomplished. In cases in which placental or colostrum transmitted antibodies cannot play a role, the young of each species—especially fowl—would require vaccination soon after birth and thus make vaccination expensive and annoying to the farmer.

5. Robins, pheasants, quail and a few other species of wild life have high infection rates and may well serve to infect mosquitoes in areas inhabited by man. The wild life group and sportsmen should gradually familiarize themselves with the facts and realize that something should be done about it. Probably, however, by controlling the domestic reservoirs the infection rate in mosquitoes and, in turn, in these wild birds will be greatly reduced. It would seem wise, however, to discontinue heavy planting of pheasants and perhaps certain other game in endemic areas. In the Yakima Valley, fourteen thousand pheasants a year are being released, and those caught in this area appear to have an infection rate approaching 50 per cent.

The control measures outlined, both for preventing the entry of a new virus and for the control of those already present, are offered at this time only as suggestions. Some of the evidence on which they are based may yet be shown to be in error or only part of the truth. Some are more or less impracticable from the administrative standpoint. Some are warranted in one area and not in another. It has been my purpose to impress those responsible for the prevention and control of disease, and those who might serve to influence them, with the immediate and pressing importance of the situation and to outline briefly the measures that could be employed, based on our present knowledge. An attempt has been made to evaluate some of these procedures. The situation has grave potentialities, threatening both civilian and military horses and personnel. It is increasing yearly in importance, and prompt, intelligent action can undoubtedly change the course of events.

University of California, San Francisco.

Council on Medical Education and Hospitals

CONTINUATION COURSES FOR PRAC- TICING PHYSICIANS

In accordance with the plan of the Council on Medical Education and Hospitals, advance information concerning continuation courses for practicing physicians available in the various centers is published quarterly. The following list of courses is presented for the period Jan. 1 to April 30, 1942. It is

hoped that this material will be of value to the practicing physician who may be planning to take postgraduate work but who does not have at hand a ready means of knowing when and where the subjects in which he is interested will be taught. It is urged that those who contemplate enrolling in any of these courses communicate as early as possible with the executive officer named in the following list as the size of classes is in many cases necessarily limited.

WILLIAM D. CUTTER, M.D.,
Secretary, Council on Medical
Education and Hospitals.

Continuation Courses for Practicing Physicians—January 1 to April 30, 1942

Institution	Courses Scheduled to Begin	Length and Content of Course	Number of Students Accepted for Each Course	Registration Fee and/or Tuition	For Detailed Information, Write to
ALLERGY					
Washington University School of Medicine and Barnes Hospital, St. Louis	April 6	2 weeks	68 ¹	\$40	Executive Secretary, American College of Physicians, 4200 Pine St., Philadelphia
Faculty of Medicine of Columbia University	April 13	3 weeks	48	\$150	Dean of the School of Medicine, Columbia University, 630 West 168th St., New York City
Roosevelt Hospital, New York	February 2	2 weeks	68 ¹	\$40	Executive Secretary, American College of Physicians, 4200 Pine St., Philadelphia
Graduate School of Medicine, University of Pennsylvania	Arranged on application	4 weeks, 40 hours	\$150	Dean, Graduate School of Medicine, University of Pennsylvania, Philadelphia
ANATOMY					
College of Medical Evangelists	Arranged on application	3 to 10 hours; elective subcourses	\$5 to \$15	Chairman, Committee on Postgraduate Education, 312 N. Boyle Ave., Los Angeles
University of Illinois College of Medicine	Arranged on application	Variable	4 or more	\$75 a semester plus cost of materials	Assistant to the Dean, University of Illinois College of Medicine, 1833 W. Polk St., Chicago
New York Medical College	Arranged on application	60 to 100 hours (surgical anatomy)	1 or more	\$150 to \$250	Dean, New York Medical College, 5th Ave. at 103th St., New York City
ANESTHESIA					
Harvard Medical School, Courses for Graduates	Arranged on application	1 month	3	\$30 ²	Assistant Dean, Harvard Medical School, 25 Shattuck St., Boston
Faculty of Medicine of Columbia University	Arranged on application ³	2 or 3 weeks	\$100 to \$150	Dean of the School of Medicine, Columbia University, 630 W. 168th St., New York City
New York Polyclinic Medical School and Hospital	Arranged on application	6 week and 3 month courses	\$150 to \$300	Medical Executive Officer, New York Polyclinic Medical School, 335 W. 50th St., New York City
New York University College of Medicine	Spring	3 weeks (immunization)	5	\$150	Assistant Dean, New York University College of Medicine, 477 First Ave., New York City
		3 weeks, mornings or full time (regional)	\$200	
ARTHRITIS					
Tufts Medical School, Postgraduate Division	March 2	6 days	\$25 ²	Chairman, Postgraduate Division, Tufts Medical School, 30 Bennet St., Boston
The Mayo Foundation, University of Minnesota and The Mayo Clinic, Rochester	April 13	1 week	20-25 ¹	\$20	Executive Secretary, American College of Physicians, 4200 Pine St., Philadelphia
Faculty of Medicine of Columbia University	March 2	5 days	4 or more	\$35	Dean of the School of Medicine, Columbia University, 630 W. 168th St., New York City
AVIATION MEDICINE					
George Washington University School of Medicine	February 5	3 days	\$35	Professor of Ophthalmology, George Washington University School of Medicine, 1335 H St., N.W., Washington, D. C.
BACTERIOLOGY					
Faculty of Medicine of Columbia University	January; February	1 month, mornings; part time courses	38	\$50	Dean of the School of Medicine, Columbia University, 630 W. 168th St., New York City
BRONCHO-ESOPHAGOGY					
Harvard Medical School, Courses for Graduates	Arranged on application	2 weeks (bronchoscopy)	\$150 ²	Assistant Dean, Harvard Medical School, 25 Shattuck St., Boston
Faculty of Medicine of Columbia University	Arranged on application	3 weeks	\$250	Dean of the School of Medicine, Columbia University, 630 W. 168th St., New York City
Temple University School of Medicine	March 16	2 weeks	\$250	Dean, Temple University School of Medicine, 3400 N. Broad St., Philadelphia
Graduate School of Medicine, University of Pennsylvania	January	2 weeks, 85 hours	\$250	Dean, Graduate School of Medicine, University of Pennsylvania, 36th and Pine Sts., Philadelphia
CARDIOLOGY					
College of Medical Evangelists.....	January 4	20 hours arranged	5-10	\$50	Chairman, Committee on Postgraduate Education, 312 N. Boyle Ave., Los Angeles
Massachusetts General Hospital and House of the Good Samaritan, Boston	February 2	2 weeks	20-30 ¹	\$40	Executive Secretary, American College of Physicians, 4200 Pine St., Philadelphia
Jewish Hospital, Brooklyn (Joint Committee on Post-Graduate Education)	January 13	5 weeks, 3 mornings a week	6	\$20	Registrar, Joint Committee on Post-Graduate Education, 1313 Bedford Ave., Brooklyn
	April 7	5 weeks, 3 mornings a week (includes applied electrocardiography)	12	\$20	

Continuation Courses for Practicing Physicians—January 1 to April 30, 1942—Continued

Institution	Courses Scheduled to Begin	Length and Content of Course	Number of Students Accepted for Each Course	Registration Fee and/or Tuition	For Detailed Information, Write to
CARDIOLOGY—Continued					
Faculty of Medicine of Columbia University	April 6	4 weeks	10 or more	\$100	Dean of the School of Medicine, Columbia University, 630 W. 168th St., New York City
New York Medical College.....	Arranged on application	8 weeks, twice a week (includes electrocardiography)	\$100	Dean, New York Medical College, 5th Ave. at 105th St., New York City
DERMATOLOGY					
Harvard Medical School, Courses for Graduates	February; April	1 month, mornings	Limited	\$40 ²	Assistant Dean, Harvard Medical School, 25 Shattuck St., Boston
	Arranged on application	2 months, twice a week (clinical myecology)	6	\$50 ²	
Tufts Medical School, Postgraduate Division	January 19	6 days	6 or more	\$25 ²	Chairman, Postgraduate Division, Tufts Medical School, 30 Bennet St., Boston
Faculty of Medicine of Columbia University	Arranged on application	6 weeks or 3 months, 3 afternoons a week	3	\$40; \$75	Dean of the School of Medicine, Columbia University, 630 W. 168th St., New York City
	Arranged on application ²	3 months or more, 3 sessions a week (histology)	12	\$75 to \$175	
		6 weeks or 3 months, 3 sessions a week (surgical)	2	\$40; \$75	
		6 weeks or 3 months, 3 sessions a week (myecology)	\$40; \$75	
DIABETES					
Tufts Medical School, Postgraduate Division	January 19	6 days	\$25 ²	Chairman, Postgraduate Division, Tufts Medical School, 30 Bennet St., Boston
Faculty of Medicine of Columbia University	March 9	5 days	4 or more	\$35	Dean of the School of Medicine, Columbia University, 630 W. 168th St., New York City
Graduate School of Medicine, University of Pennsylvania	Arranged on application	2 to 4 weeks, 75 hours	\$150	Dean, Graduate School of Medicine, University of Pennsylvania, Philadelphia
ELECTROCARDIOGRAPHY					
Tufts Medical School, Postgraduate Division	January 26	3 days (advanced course)	\$20 ²	Chairman, Postgraduate Division, Tufts Medical School, 30 Bennet St., Boston
Faculty of Medicine of Columbia University	April 7	4 weeks, twice a week (fundamentals)	4 or more	\$50	Dean of the School of Medicine, Columbia University, 630 W. 168th St., New York City
ENDOCRINOLOGY					
Jewish Hospital, Brooklyn (Joint Committee on Post-Graduate Education)	April	5 weeks, twice a week	4	\$20	Registrar, Joint Committee on Post-Graduate Education, 1313 Bedford Ave., Brooklyn
Faculty of Medicine of Columbia University	February 2	8 weeks, 3 afternoons a week (diseases of metabolism)	6 or more	\$40	Dean of the School of Medicine, Columbia University, 630 W. 168th St., New York City
	March 16	2 weeks	6 or more	\$50	
New York Medical College.....	Arranged on application	4 weeks, 36 hours	\$100	Dean, New York Medical College, 5th Ave. at 105th St., New York City
FORENSIC MEDICINE					
New York University College of Medicine	Arranged on application	1 month or more	\$25 to \$100	Assistant Dean, New York University College of Medicine, 477 First Ave., New York City
GASTROENTEROLOGY					
University of Chicago, The School of Medicine, Billings Hospital	April 6	2 weeks	30-75 ¹	\$40	Executive Secretary, American College of Physicians, 4200 Pine St., Philadelphia
	Arranged on application	2 week and 3 month courses in gastroscopy	3; 1	\$100 to \$150	Dean of Students, University of Chicago, The School of Medicine, Chicago
Tufts Medical School, Postgraduate Division	February 9	6 days	\$25 ²	Chairman, Postgraduate Division, Tufts Medical School, 30 Bennet St., Boston
Greenpoint Hospital, Brooklyn (Joint Committee on Postgraduate Education)	February 2	6 weeks, twice a week	4	\$10	Registrar, Joint Committee on Post-Graduate Education, 1313 Bedford Ave., Brooklyn
Jewish Hospital, Brooklyn (Joint Committee on Postgraduate Education)	April 7	4 weeks, twice a week	8	\$10	
Faculty of Medicine of Columbia University	Arranged on application ²	2 months, 3 afternoons a week (gastroscopy)	1	\$200	Dean of the School of Medicine, Columbia University, 630 W. 168th St., New York City
	April 6	4 weeks	10 or more	\$100	
New York Medical College.....	Arranged on application	10 sessions (gastroscopy)	\$100	Dean, New York Medical College, 5th Ave. at 105th St., New York City
New York Polyclinic Medical School and Hospital	January 2; April 1	6 weeks	\$75 to \$100	Medical Executive Officer, New York Polyclinic Medical School, 325 W. 50th St., New York City
Hahnemann Medical College and Hospital	Arranged on application	1 month or more	Varies	Head of Department of Gastroenterology, Hahnemann Medical College, Philadelphia
Graduate School of Medicine, University of Pennsylvania	Arranged on application ²	16 weeks, 500 hours	\$400	Dean, Graduate School of Medicine, University of Pennsylvania, Philadelphia

A limited number of opportunities for postgraduate study in the clinical departments are also offered by the University of Chicago, The School of Medicine, Tulane University of Louisiana School of Medicine, Johns Hopkins University School of Medicine, Duke University School of Medicine, Vanderbilt University School of Medicine, Meharry Medical College, and the University of Wisconsin Medical School.

1. The courses are organized especially for Fellows and Associates of the American College of Physicians, but where facilities are available, courses will be open to those with adequate preliminary training who are now preparing either to meet the requirements of membership in the College or certification by the American Board of Internal Medicine.

2. Registration fee of \$5 covers all courses taken within twelve months.

3. Admission is limited to physicians who have had adequate previous training and experience in the special field.

4. A faculty course given for staff members of mental institutions.

5. State boards of health furnish either the funds covering tuition fees, maintenance or transportation for physicians of the state.

6. Trainees are usually recommended by state or city health departments.

7. Applicants may qualify for a monthly stipend from the United States Public Health Service.

8. Short course scheduled on arrangement of health department or agency, one month course on an individual basis.

CHICAGO, Feb. 16-17, 1942. Council on Medical Education and Hospitals, Sec., Dr. William D. Cutter, 535 North Dearborn Street, Chicago.

MEDICAL CORPS, UNITED STATES NAVY

Examination. Assistant Surgeon with the permanent rank of Lieutenant (junior grade) and Acting Assistant Surgeon with the probationary rank of Lieutenant (junior grade), Jan. 5-9. Examination will be held at the Naval Hospitals at Chelsea, Mass., Newport, R. I., Brooklyn, Philadelphia, Norfolk, Va., Charleston, S. C., Pensacola, Fla., Corpus Christi, Tex., San Diego and Mare Island, Calif., Puget Sound, Wash., Great Lakes, Ill., Pearl Harbor, T. H., and Naval Medical Center, Washington, D. C. Apply Bureau of Medicine and Surgery, Navy Department, Washington, D. C.

NATIONAL BOARD OF MEDICAL EXAMINERS EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and Examining Boards in Specialties were published in THE JOURNAL, December 27, page 2272.

BOARDS OF MEDICAL EXAMINERS

ALABAMA: Montgomery, June 16-18. Sec., Dr. B. F. Austin, 519 Dexter Ave., Montgomery.

ARIZONA: * Phoenix, Jan. 6-7. Sec., Dr. J. H. Patterson, 826 Security Bldg., Phoenix.

ARKANSAS: * Little Rock, June 4-5. Sec., Dr. D. L. Owens, Harrison. CONNECTICUT: * Medical Examination. Hartford, March 10-11. Endorsement. Hartford, March 24. Sec. to the Board, Dr. Creighton Barker, 258 Church St., New Haven. Homopathic. Derby, March 10-11. Sec., Dr. Joseph H. Evans, 1438 Chapel St., New Haven.

DELAWARE: Dover, July 14-16. Sec., Medical Council of Delaware, Dr. Joseph S. McDaniel, 229 S. State St., Dover.

FLORIDA: * Jacksonville, June 22-23. Sec., Dr. William M. Rowlett, Box 786, Tampa.

GEORGIA: Atlanta, June. Sec., State Examining Boards, Mr. R. C. Coleman, 111 State Capitol, Atlanta.

HAWAII: Honolulu, Jan. 12-15. Sec., Dr. James A. Morgan, 48 Young Bldg., Honolulu.

IDAHO: Boise, Jan. 13. Dir., Bureau of Occupational License, Mr. Walter Curtis, 355 State Capitol Bldg., Boise.

ILLINOIS: Chicago, Jan. 20-22. Superintendent of Registration, Mr. Philip M. Harman, Department of Registration and Education, Springfield.

INDIANA: Indianapolis, June 16-18. Sec., Board of Registration and Examination, Dr. J. W. Bowers, 301 State House, Indianapolis.

IOWA: * Des Moines, Jan. 15-17. Dir., Division of Licensure and Registration, State Department of Health, Mr. H. W. Grefe, Capitol Bldg., Des Moines.

MAINE: Portland, March 10-11. Sec., Board of Registration of Medicine, Dr. Adam P. Leighton, 192 State St., Portland.

MASSACHUSETTS: Boston, March 10-13. Sec., Board of Registration in Medicine, Dr. Stephen Rushmore, 413-F State House, Boston.

MICHIGAN: * Ann Arbor and Detroit, June 10-12. Sec., Board of Registration in Medicine, Dr. J. Earl McIntyre, 202-4 Hollister Bldg., Lansing. MINNESOTA: * Minneapolis, Jan. 20-22. Sec., Dr. Julian F. Du Bois, 230 Lowry Medical Arts Bldg., St. Paul.

MONTANA: Helena, April 7-8. Sec., Dr. Otto G. Klein, First National Bank Bldg., Helena.

* NEVADA: Reciprocity. Carson City, February 2. Sec., Dr. Frederick M. Anderson, 215 N. Carson Street, Carson City.

NEW HAMPSHIRE: Concord, March 12-13. Sec., Dr. T. P. Burroughs, Board of Registration in Medicine, State House, Concord.

NEW JERSEY: Trenton, June 16-17. Sec., Dr. Earl S. Hallinger, 28 W. State St., Trenton.

NEW MEXICO: * Santa Fe, April 13-14. Sec., Dr. Le Grand Ward 135 Sena Plaza, Santa Fe.

NEW YORK: Albany, Buffalo, New York and Syracuse, Jan. 26-29. Chief, Bureau of Professional Examinations, Mr. Herbert J. Hamilton, State Education Department, 315 Education Bldg., Albany.

NORTH DAKOTA: Grand Forks, Jan. 6-9. Sec., Dr. G. M. Williamson, 4½ S. Third St., Grand Forks.

OREGON: Portland, Jan. 21-23. Exec. Sec., Miss Lorianne M. Conlee, 608 Failing Bldg., Portland.

PENNSYLVANIA: Philadelphia, Jan. 6-10. Acting Sec., Bureau of Professional Licensing, Mrs. Marguerite G. Steiner, 353 Education Bldg., Harrisburg.

RHODE ISLAND: * Providence, Jan. 8-9. Chief, Division of Examiners, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

SOUTH DAKOTA: * Pierre, Jan. 13-14. Dir., Medical Licensure, Dr. J. F. D. Cook, State Board of Health, Pierre.

TEXAS: Galveston, March 23-25. Sec., Dr. T. J. Crowe, 918-20 Texas Bank Bldg., Dallas.

VERMONT: Burlington, Feb. 10-12. Sec., Board of Medical Registration, Dr. F. J. Lawless, Richmond.

WEST VIRGINIA: Charleston, March 24. Commissioner, Public Health Council, Dr. C. F. McClinton, State Capitol, Charleston.

WASHINGTON: * Seattle, Jan. 12-14. Dir., Department of Licenses, Mr. Thomas A. Swayze, Olympia.

WISCONSIN: * Madison, Jan. 13-15. Sec., Dr. H. W. Shutter, 425 E. Wisconsin Ave., Milwaukee.

WYOMING: Cheyenne, Feb. 2-3. Sec., Dr. M. C. Keith, Capitol Bldg., Cheyenne.

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

CONNECTICUT: Feb. 14. Address State Board of Healing Arts, 1945 Yale Station, New Haven.

DISTRICT OF COLUMBIA: Washington, April 20-21. Sec., Commission on Licensure, Dr. George C. Ruhland, 6150 E. Municipal Bldg., Washington.

FLORIDA: Gainesville, June 8. Sec., Professor J. F. Conn, John B. Stetson University, De Land.

IOWA: Des Moines, Jan. 13. Dir., Division of Licensure and Registration, State Department of Health, Mr. H. W. Grefe, Capitol Bldg., Des Moines.

MICHIGAN: February 13-14. Sec., Miss Flora E. Dube, East Lansing.

MINNESOTA: Minneapolis, Jan. 6-7. Sec., Dr. J. Charnley McKinley, 126 Millard Hall, University of Minnesota, Minneapolis.

NEBRASKA: Omaha, Jan. 13-14. Dir., Bureau of Examining Boards, Mrs. Jeannette Crawford, 1009 State Capitol Bldg., Lincoln.

NEW MEXICO: Albuquerque, Feb. 2. Sec., Miss Pia Joerges, State Capitol, Santa Fe.

OREGON: Portland, Feb. 14. Applications must be on file not later than Jan. 28. Sec., State Board of Higher Education, Mr. Charles D. Byrne, University of Oregon, Eugene.

RHODE ISLAND: Providence, Feb. 18. Chief, Division of Examiners, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

WASHINGTON, Seattle, Jan. 8-9. Dir., Department of Licenses, Mr. Thomas A. Swayze, Olympia.

Texas June Report

The Texas State Board of Medical Examiners reports the written examination for medical licensure held at Austin, June 16-18, 1941. The examination covered 12 subjects and included 120 questions. An average of 75 per cent was required to pass. One hundred and seventy-one candidates were examined, 162 of whom passed and 9 failed. Sixty-one physicians were licensed to practice medicine by reciprocity and 2 physicians so licensed by endorsement. The following schools were represented:

School	PASSED	Year Grad.	Number Passed
Rush Medical College.....	(1939)		1
Tulane University of Louisiana School of Medicine.....	(1941)		1
Washington University School of Medicine.....	(1940)		1

Wisconsin June Report

The Wisconsin State Board of Medical Examiners reports the written examination for medical licensure held at Milwaukee, June 24-26, 1941. The examination covered 19 subjects and included 100 questions. An average of 75 per cent was required to pass. One hundred and four candidates were examined, all of whom passed. Twenty-eight physicians were licensed to practice medicine by reciprocity. The following schools were represented:

School	PASSED	Year Grad.	Number Passed
College of Medical Evangelists.....		(1941)	1
Loyola University School of Medicine.....		(1941)	1

* Licenses have not been issued.

† Examined in surgery.

Montana October Report

The Montana State Board of Medical Examiners reports the written examination for medical licensure held at Helena, Oct. 6-8, 1941. The examination covered 10 subjects. An average of 75 per cent was required to pass. Two candidates were examined, both of whom passed. Eight physicians were licensed to practice medicine by reciprocity and 2 physicians so licensed on endorsement of credentials of the National Board of Medical Examiners. The following schools were represented:

School	PASSED	Year Grad.	Number Passed
George Washington University School of Medicine....		(1910)	1
Université de Lausanne Faculté de Médecine.....		(1937)	1

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with

* Examined in surgery.

Bureau of Legal Medicine
and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice: Fraudulent Concealment as Affecting Statute of Limitations.—In March 1929 the defendant dentist removed an impacted wisdom tooth, and an attached pus sac, from the plaintiff's lower left jaw and a few months later also extracted her lower right wisdom tooth. She continued to have headaches and pain in various parts of her body, however, and consulted the defendant again the latter part of 1929 but was advised that she was not suffering from any infection due to her teeth. During the next several years the plaintiff consulted many doctors and submitted to operations for the removal of her tonsils, appendix and gallbladder, but the pain in her face continued. In March 1938 a roentgenogram taken by some dentist other than the defendant revealed two fragments of tooth root in the plaintiff's lower left jaw bone. These were removed and the plaintiff gradually regained her health. In a subsequent suit against the defendant for malpractice, the jury returned a verdict for the defendant, and the plaintiff appealed to the Supreme Court of Errors of Connecticut.

The plaintiff contended that the defendant had fraudulently concealed from her the existence of the broken pieces of tooth in her jaw and that therefore the defense of the statute of limitations was not available. The Supreme Court of Errors said that, in order for the plaintiff to sustain her contention, she was required to prove that the defendant had actual or constructive knowledge that the fragments of tooth remained in the plaintiff's jaw after the extraction. Without such knowledge there could be no fraudulent concealment. The plaintiff testified that the defendant showed her the tooth after it had been extracted and called her attention to the pus sac attached thereto. Nothing was then said or done by the defendant which indicated a knowledge that any part of the tooth still remained in her jaw. Furthermore, there was no expert testimony supporting the theory that, in the exercise of due care and skill, the defendant should have known that the fragment remained. The court therefore held that there was nothing in the record to indicate a finding that the defendant either knew or should have known of such condition or that he was guilty of a gross want of due care. The court further held that the plaintiff could not rely on the doctrine of *res ipsa loquitur*. Such doctrine could be applied to infer negligence only when there were some facts proved which afforded a basis for such inference. Here there were no such facts shown. Applied to this case, therefore, the doctrine would only infer negligence in failing to discover that the fragments remained rather than an actual knowledge thereof. The judgment for the defendant was therefore affirmed.—*Frogge v. Shugrue*, 13 A. (2d) 503 (Conn., 1940).

Medical Practice Acts: Graduates from Foreign Medical Schools; Foreign Licensure Requirement.—The plaintiff, a citizen of the United States and a resident of the state of California, received one year of medical instruction at the University of Albert-Ludwig in Germany and then concluded his medical studies at the University of Basle in Switzerland. He then returned to the United States and served an eighteen months internship in the Los Angeles County General Hospital. The evidence showed that the medical schools which the plaintiff attended and the hospital in which he interned were all approved by the defendant board as proper places for instruction and internship. When the plaintiff subsequently petitioned the defendant, the Board of Medical Examiners of the State of California, for permission to take the regular examination for a physician's and surgeon's license, however, he was denied that right on the ground that he had failed to show that he was licensed to practice medicine in Switzerland. The plaintiff filed

a petition for a writ of mandamus to compel the board to permit him to take the examination. The trial court found in favor of the plaintiff and the defendant appealed to the district court of appeal, second district, division 2, California.

The Business and Professions Code of California (Section 2193) requires that a person whose application for examination is based on a diploma issued by a foreign medical school must show, among other things, that

(c) He has been admitted or licensed to practice medicine and surgery in the country where the institution in which he has pursued his medical course of professional instruction is located.

The plaintiff contended that this requirement constituted an unreasonable, arbitrary and discriminatory exercise of the police power. It was necessary to determine, said the district court of appeal, whether or not the legislature intended the requirement to apply both to aliens and to American citizens. The court found that it was impossible for an American citizen to obtain a license to practice medicine in Switzerland and that, because of this inability, an alien applicant who had attended a foreign school was in a better position before the California board than was a citizen who had so attended, because the alien was able to obtain a license to practice in his native country. To the court it seemed unreasonable to believe that the legislature intended such an unjust result. The court therefore assumed that the legislature had been properly informed on the subject matter of the requirement and knew, at the time Section 2193 (c) was enacted, that American citizens were unable to obtain the required foreign license. It therefore concluded that the legislature must have meant the requirement to apply only to alien petitioners. Any other holding, said the court, would result in an injustice and an absurdity. The judgment for the plaintiff was accordingly affirmed.—*Leo v. Board of Medical Examiners*, 97 P. (2d) 1046 (Calif., 1940).

Malpractice: Liability of Physician for Negligence of Nurse.—One of the plaintiffs, Mrs. Kelly, took her infant son to the office of the defendant physician for an examination. While she was waiting her turn to see the doctor, a nurse employed by the defendant requested her to assist in holding a child on the x-ray table. The nurse-technician was in sole charge of the x-ray room and apparatus. In order to do this, Mrs. Kelly was directed to take a position between the x-ray table and the wall, touching both, with her hands on the child's ankles. She noticed that the child's ankles were wet but was advised that that was a matter of no importance. While Mrs. Kelly was thus acting as requested, the nurse turned on the electric current. Instantly there was a flash and a spark from the mechanism to Mrs. Kelly's head, the light in the x-ray machine immediately went out and Mrs. Kelly fell to the floor. She was both burned by the electric current and injured by the fall. Subsequently the plaintiffs, Mr. and Mrs. Kelly, sued the defendant physician for damages alleged to have been caused by the negligence of the defendant's nurse. From a judgment in favor of the plaintiffs, the defendant appealed to the Supreme Court of Pennsylvania.

The defendant contended that the judgment should be reversed because there was no evidence of any negligence chargeable to him. The Supreme Court said that when a physician burns a patient in the course of a roentgen treatment no prima facie liability attaches because burns do occur occasionally in the ordinary course of an exposure in spite of the highest degree of diligence and care to prevent them. In such a case the patient, in order to recover damages, must show that the apparatus was different from that ordinarily used or that the technician was incompetent to use it. The wife-plaintiff, however, continued the court, was not a patient of the defendant at the time she received her injuries. She was acting at the request and under the direction of the defendant's agent and thus did not assume the risks which a patient had to assume. When a thing which causes an injury is shown to be under the management of the defendant, the Supreme Court continued, and the accident is such as in the ordinary course of things does not

happen if those who have the management use proper care, it affords reasonable evidence, in the absence of any explanation by the defendants, that the accident arose from such want of care. The effect of this principle is to require the defendant, in a case of this nature, to produce affirmative proof of his own freedom from fault. No such evidence was produced on behalf of the defendant, and the jury was justified, in the opinion of the court, in finding that the nurse was negligent.

The Supreme Court further found that the nurse-technician was the defendant's servant and that the taking of roentgenograms was within the scope of her employment. Moreover, her implied authority included the control of the patient as well as the actual operation of the apparatus. Her act in inducing the wife-plaintiff to assist her was thus incidental to the defendant's business and in furtherance of it, said the court, even though it was not specifically authorized. The defendant was therefore responsible for the consequences of her act. The judgment for the plaintiffs was accordingly affirmed.—*Kelly et al. v. Mount*, 7 A. (2d) 582; 12 A. (2d) 579 (Penn., 1940).

Workmen's Compensation Acts: Compensability for Death Due to Bacillus Enteritidis.—The duties of the employee consisted of skinning and butchering animals for use in the manufacture of chicken feed and other animal by-products. On Aug. 10 or 12, 1937, he became ill while at work and died twelve days later, death being attributed to Bacillus enteritidis. An award of compensation was denied by the industrial commission, and the widow of the employee appealed to the Supreme Court of Utah.

The workmen's compensation act of Utah provides that "(5) 'Personal injury by accident arising out of or in the course of employment' . . . shall not include a disease, except as it shall result from the injury." The defendant contended that the employee did not die as the result of an accident within the meaning of the act but rather as the result of a disease. The Supreme Court said that an accident is not limited in meaning to the application of physical force to the body of the injured but that infection by germs may be an accidental or unexpected event, even though not preceded by physical force. On the other hand, the Court continued, an illness is not compensable merely because it is contracted while the employee is engaged in his usual occupation; there still has to be a definite causal connection between the employment and the illness. The Court found that the disease from which the employee in this case died was rare and uncommon. It was contracted from diseased meat and the employee came in contact with such meat at the place he worked. The only reasonable conclusion, held the Supreme Court, was that the employee contracted the disease in the course of his employment. Judgment for the defendant was therefore reversed and the cause remanded for further proceedings.—*Andreason v. Industrial Commission*, 100 P. (2d) 202; 102 P. (2d) 894 (Utah, 1940).

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1931 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Comparison of Types of Insulin.—Duncan and Barnes state that there is evidence that globin insulin acts with sufficient rapidity to prevent hyperglycemia during the day and that its action is sufficiently prolonged to control the level of the blood sugar throughout the night. Before they attempted the routine treatment of diabetic patients with globin insulin they determined the time of onset, the intensity and the duration of the hypoglycemic effect produced in 42 patients by a single injection and compared the results with those produced by single doses of the insulins now in common use. The globin insulin, in all but 1 of the subjects studied, had a blood sugar lowering action which began within two hours of its injection. This effect reached a maximal intensity between the second and the eighth hour and was maintained for eighteen to twenty-four hours. The hypoglycemic action during the first four hours was slower than that of unmodified and crystalline insulin but more rapid than that of protamine zinc insulin. The period of maximal effect began sooner and ceased earlier than that following the administration of protamine zinc insulin. Thus the tendency of the more rapid action of globin insulin to prevent postcibal hyperglycemia would obviate the need of supplemental doses of unmodified or crystalline insulin. The lowest level of blood sugar was reached between the eighth and the tenth hour after the administration of globin insulin. Thus patients receiving globin insulin routinely are prone to have hypoglycemic reactions between 4 p. m. and dinner time unless appropriate dietary rearrangements are made to prevent them. Patients who received moderately large doses of insulin had slightly greater hypoglycemic effects from the globin than from the protamine zinc insulin, indicating that unit for unit globin insulin has a greater hypoglycemic effect than protamine zinc insulin.

Rabbit Thrombin as Local Hemostatic.—Lozner and his associates observed the effect of rabbit thrombin on 11 patients bleeding from small wounds. Nine of the patients had hemorrhagic diatheses (4 had hemophilia, 3 symptomatic thrombocytopenic purpura, 1 hypoprothrombinemia and 1 hereditary thrombasthenia) and 2 patients had hypertension with epistaxis. Dry, powdered rabbit thrombin was usually used to impregnate a dressing, pack or "gauze bite" dampened with sterile saline solution. The dry powder comes into immediate contact with the bleeding surface. With only one exception the hemostasis produced by rabbit thrombin was complete and immediate. That is, as soon as the dressing was applied hemorrhage was arrested. In 1 patient with hypertension and epistaxis bleeding had persisted for fourteen days prior to rabbit thrombin therapy, despite the use of various hemostatics and four blood transfusions. The patient in whom hemostasis was at first only partial had complete and immediate hemostasis after two subsequent applications on succeeding days. The unsatisfactory result of the first application was probably due to error in application. Rabbit thrombin solution was also of value as a local hemostatic but was not as effective as the dry powder. There were no toxic effects after the use of either form of thrombin. The hemostatic effect of rabbit thrombin is apparently accomplished by its instantaneous precipitation of fibrin.

Pregnancy Toxemias in Relation to Vascular Damage.—Peckham followed up 500 women whose pregnancy was complicated by toxemia to determine whether the time of onset and the duration before parturition are of importance in the development of permanent vascular damage. The follow-up study after parturition consisted in examinations at intervals of three months for two to twelve years. All the women were apparently normal when first seen in the antepartum clinic. The race and age of the patient, the degree of hypertension, the degree of albuminuria during pregnancy, the type of delivery and the result to the child had no significant bearing on the month in which toxemia developed. The incidence of multiparas increased as the onset of the toxemia took place in the earlier months of gestation. If the toxemia was manifest near the beginning of gestation the number of abnormally high blood pressure readings increased, both at the time of the patient's discharge from the hospital and six weeks post partum. The incidence of previous toxemia was higher in patients evidencing toxemia early in pregnancy than in those whose first abnormality occurred in the later months. There was a similar trend in subsequent pregnancies. The incidence of chronic vascular damage was 63.4 per cent. The percentage was 89.93 among multiparas and 32.76 among primiparas. Vascular damage was always seen in the primipara whose toxemia occurred prior to the sixth month of gestation. Multiparas had vascular damage if the toxemia occurred prior to the eighth month. Vascular damage

occurred in the primipara who had been carried for more than twelve weeks after toxemia developed; the limit for multiparas was six weeks. It seems that the duration of a toxemia is of more importance in relation to subsequent vascular disease than the month of onset. Termination of the pregnancy to avoid chronic damage appears justified if signs and symptoms persist after four weeks of observation and treatment.

Vitamin Therapy in Vulvar Dermatoses.—Hesseltine observed the responses of 15 patients with chronic atrophic dermatitis of the vulva, 5 with an undetermined type of vulvitis and 2 with unexplained vulvar pruritus to single and combined factors of the vitamin B complex. The oral route was used almost exclusively. According to the usual standards, 19 of the 22 patients were apparently free of vitamin deficiency, 1 existed on an inadequate diet, 1 had a faulty or inadequate absorption and 1 suffered from a protracted and unusual infection with multiple draining areas. If improvement did not follow thiamine hydrochloride therapy other components of the B complex were added. Therapy with the vitamin B complex did not eradicate vitiligo or correct advanced chronic atrophic dermatitis of the vulva, although symptoms were partially or completely relieved and fissures and leukoplakic areas disappeared. On the other hand the first stage of chronic atrophic vulvitis and certain types of undetermined vulvitis cleared up after treatment with thiamine hydrochloride, thiamine hydrochloride and riboflavin or multiple factors of the B complex. There was a tendency to recurrence in a few of the patients whose symptoms were alleviated (cured), possibly because of the premature withdrawal of the vitamins, some imbalance in metabolism or some other state. Small maintenance doses may be needed. The administration of factors of the B complex for chronic atrophic dermatitis of the vulva is not yet endorsed except for persons in such poor health they cannot be operated on and for patients with a vulvitis for which there is no specific therapy. If chronic irritation can be relieved perhaps the incidence of malignant growths might be reduced.

Amphetamine Sulfate as Corrective in Epilepsy.—Robinson gave amphetamine sulfate to 58 epileptic patients to circumvent the untoward toxic effects (irritability, drowsiness, ataxia, aggressiveness, anorexia, vertigo, nystagmus and tremor) of anticonvulsant therapy. The therapy usually consisted of phenobarbital. The daily dose of amphetamine sulfate ranged from 5 to 30 mg. It was given orally. The drug counteracted the drowsiness in 39, or 64.2 per cent, of the 56 patients having this manifestation. It combated along with the drowsiness the ataxia in 3 of 13 patients. It counteracted irritability in

3 of 15 patients. Giving amphetamine sulfate did not usually correct aggressiveness. It was necessary to give amphetamine sulfate only temporarily to patients who slowly acquire a tolerance to large doses of phenobarbital. In such patients it overcame the toxic symptoms until tolerance was established, when it could be withdrawn. In other patients, toxic phenomena reappeared unless the amphetamine sulfate therapy was continued as long as the phenobarbital medication was not reduced. In no case did the use of amphetamine sulfate alter the incidence of seizures. What it did do was to make it possible to reduce seizures in many patients by giving them adequate anticonvulsant medication without toxic manifestations forcing discontinuance.

Iontophoresis of Copper Sulfate for Mycotic Infection.—Greenwood and Rockwood say that for their 4 patients from whom material which produced cultures of identifiable fungous organisms was obtained from affected areas at their first visit the introduction of copper sulfate into the skin by iontophoresis was neither fungicidal nor fungistatic for the three pathogens found: *Trichophyton gypseum*, *Trichophyton purpureum* and *Epidermophyton inguinale*. When clinical improvement follows such treatment it must be due to some factor or factors other than the copper sulfate. One of the patients was given twenty-five treatments, and still it was possible to grow *T. gypseum* from scales taken at each examination and at the patient's last visit. In another patient the process was extending so rapidly after the sixth iontophoresis that compound ointment of benzoic acid was applied for ten days, and since then there

has been no obvious activity and all scales and cultures have been negative for *T. gypseum*. The third patient was treated for a month, and culture for *E. inguinale* was positive after each treatment. After treatment with compound ointment of benzoic acid the condition was clinically improved but still active mycologically for *E. inguinale*. The fourth patient was treated with copper sulfate iontophoresis for thirty-three days, and culture of material obtained during and at the conclusion of treatment showed *T. purpureum*.

Ringworm of Feet.—Jamieson and McCrea found known organisms in scrapings from the shoes of 40 per cent of patients with ringworm of the feet; the specimens from 25 per cent were definitely not infected, and those from 34 per cent were doubtfully infected. The organisms found in the shoes varied in number and type according to the length of time the shoe had been worn, the severity of the infection, the care and protection given the feet and the frequency with which stockings were changed. A study of whether the pathogen found in the scrapings from the skin and that in scrapings from the soles of the shoes were the same revealed accepted pathogens (*Trichophyton*, *Microsporon* and *Epidermophyton*) in the skin of 18 of 25 patients but in the scrapings from the shoes of only 12. The scrapings from the shoes of these 12 showed the same organisms found in cultures of scrapings from the skin. The number of possible pathogenic fungi (*Monilia*, *Actinomyces*, *Torula*, yeast and *Penicillium brevicaulis*) found in scrapings from the skin and from shoes was nearly equal, twenty and twenty-one respectively. In addition to the accepted and possible pathogens, various accepted nonpathogenic organisms were revealed in fourteen cultures of scrapings from the skin and in thirty-one cultures of scrapings from shoes. This result seems natural if the lack of care the shoe receives compared with that given the foot is considered.

Sulfaguanidine for Proctitis.—Cañizares and Morris used sulfaguanidine for the treatment of 6 patients with proctitis due to venereal lymphogranuloma. The daily dose of the drug was 24 Gm., divided into four equal doses. The period of treatment varied from twenty-seven to forty-seven days. All patients with simple inflammatory proctitis experienced subjective and objective improvement. Patients with narrow fibrotic stricture of the rectum were not improved; to them the drug was given preoperatively as a preparatory measure. Chemotherapy will not do more than heal erosions and ulcerations.

Intraventricular Drainage for Cystic Craniopharyngioma.—Scarff treated 7 patients with suprasellar cysts by internal drainage into the cerebral ventricles. The basic principle of the new method is that it establishes a communication between the dome of the cyst and the floor of the lateral ventricle. Such an opening, if adequately made, will probably remain patent, allowing permanent drainage of the secretions issuing from the lining of the cyst into the cerebrospinal fluid, which carries away the secretions in its regular circulation. In selected instances (with a cystic craniopharyngioma large

enough to push up and thin out the floor of the lateral ventricles) the method promises better results than those that have been obtained by draining the contents of the cyst.

Phenytoin Hyperplastic Gingivitis.—Ziskin and his associates studied the gums of 14 epileptic patients, aged from 9 to 44 years, taking phenytoin sodium daily. Three boys, aged 8, 13 and 17 years, respectively, whose seizures were controlled with phenobarbital, were included for comparison. The chief complaints of the patients receiving phenytoin sodium were bleeding from the gums, enlargement of the gums and difficulty in mastication. Without therapy, phenytoin gingivitis progresses steadily. As proliferation progresses, the teeth are moved out of their natural alignment, and the interseptal bone may be resorbed, producing looseness and sometimes loss of the teeth. If the hyperplastic tissue is extracted the appearance of the gums returns to normal for a time without further treatment. Vigorous massage of the interdental papillae or surgical intervention followed by massage was more successful. Gingival treatment should probably be begun when phenytoin therapy is started. Administration of the drug need not be discontinued because of the gingival hyperplasia. Other sedatives used in the control of epileptic seizures do not stimulate the gums to hyperplasia. The resemblance of the phenytoin gingival hyperplasia to the hypertrophy seen in scurvy is superficial; the hypertrophy in scurvy is caused by swelling and not by hyperplasia as it is in phenytoin gingivitis. Pain, marginal necrosis of the gums and occasional petechial hemorrhage are absent in phenytoin hyperplasia, as are constitutional purpura and soreness of the joints.

Ethmosphenoidal Epiglottidean Syndrome and Voice Dynamics.—Felderman describes an impairment of the vocal mechanism, ethmosphenoidal epiglottidean syndrome, that he encountered over a decade in 67 patients. He believes the syndrome to be more frequent than his observations indicate. The patients complain, usually in the morning, that they are not in "good voice." The alteration in voice and the hoarseness clear up during the day. Vocalization and swallowing usually clear up the effete mass that has accumulated during the night. The patient finds it difficult to start phonation, and his throat tires quickly. Pus may be found in the nasopharynx. Partial or total loss of taste or smell, a ticklish and tight feeling about the throat and blocking of the ears, with or without spasmodic cough, are some of the symptoms. Indirect pressure on Jacobson's nerve may give rise to otic symptoms. Patients with the syndrome also show a faint redness of the tympanic membrane, with or without a corresponding impairment in hearing. Less frequently they hear tingling bells, an echo, a vibration or the reechoing of a note in lesser or greater intensity. Another group of symptoms, mostly pharyngeal, arises when the muscles of the pharynx and its nerve supply are involved. If pressure on the laryngeal structure from even a trivial amount of pus is present it is sufficient to interfere with the normal emission of sounds. In the beginning the patient may rid himself of the pus by coughing. Later pus accumulates in larger quantities and remains in evidence when the epiglottis is examined. The accumulated pus pressing on the vallecula of the epiglottis is sufficient to upset the normal working balance of the intrinsic group of muscles. To a singer, the "head cold," if not treated properly, is one of the most devastating of human maladies, as it may leave an infective focus in the ethmosphenoidal area.

The syndrome has been mistakenly diagnosed as pachydermia of the larynx, prolapse of the laryngeal ventricle, singers' nodules, hemorrhage of the vocal cords, arthritis, perichondritis of the larynx, thyroid disorders, syphilis and as early tuberculosis and cancer of the larynx. It takes eight to ten weeks for the voice to become normal again after surgical or non-surgical treatment. The downward gravitation of the infection into the many inaccessible and complex structures makes it difficult to eradicate. When a mechanical obstruction exists the most essential and conservative surgical intervention is indicated. Infected tonsils should be removed and dental caries treated. In formulating a plan of non-surgical treatment, one should correct any endocrine and vitamin deficiencies and allergic tendencies. Autogenous vaccine has been helpful. A mild germicide (0.2 or 0.1 of 1 per cent silver picrate in 7.5 per cent dextrose solution) will diminish the production of pus without paralyzing the ciliary activity of the nose.

Industrial Manganese Poisoning.—According to Flinn and his co-workers, 11 of 34 men who had worked or were working in an atmosphere containing manganese had varying degrees of chronic manganese poisoning. Ten of the 11 men complained of lassitude, drowsiness, tremor of the body or the extremities, disturbances of gait and slight dyspnea; 9 of muscular weakness and muscular cramps; 8 of disturbances in speech and sexual function; 7 of metallic taste; 6 of vertigo, paresthesia and palpitation; 5 of loss of appetite, muscular pain, twitching of fingers and headache; 4 of articular pains and increased perspiration; 3 of salivation, impulsive weeping and laughter, and 2 of difficulty in swallowing, violent temper and nausea. A low leukocyte count with a reduced percentage of neutrophilic leukocytes was a significant finding, but the authors do not know whether or not this occurs early enough to be used as a criterion for removing a worker from exposure to manganese. As with other occupational diseases, the first step in the diagnosis is to obtain the occupational history and knowledge of any diseases associated with such a history. From the study of the course of the 11 patients it appears that many of the symptoms will disappear or regress if the worker is removed from contact with manganese shortly after the onset of symptoms. Some residual disturbances in gait and speech may remain. Well advanced manganese poisoning is a permanent crippling disease, particularly of the legs. Many of the symptoms will improve slowly, with occasional remissions, but the use of the legs is only partially recovered. Quarterly physical examinations should be made of all employees who work in an atmosphere of manganese dust, and any workers showing signs of early poisoning (drowsiness, languor, muscular cramps, twitching or tremor) should be transferred to an environment free of manganese until the hazard has been controlled. Later symptoms and signs (disturbances in gait and speech) may mean that the disease has progressed too far to be relieved by removing the subject from exposure to manganese. Engineering control methods in general use in dusty trades are effective in preventing the dispersal of manganese dusts.

Bacteremia Produced by Aerobic Bacillus.—Bondi and his associates isolated an aerobic, gram-negative, spore-forming bacillus from the blood of 5 hospitalized patients. The bacillus had no serologic relationship to *Alcaligenes fecalis*. Over a period of five months the bacillus was isolated nine times: once from each of 3 patients, twice from 1 and four times from 1 patient. It was isolated also from the bone marrow and from the spleen at the necropsy of the last patient nine days after the last blood culture was made. The strains in all 5 patients were identical; evidently they comprised a single species. The consistency with which this bacillus was isolated in cultures of blood from the 1 patient convinced the authors that they were not dealing with an ordinary contaminant but with an actual inhabitant of the blood stream. They describe this bacillus and report the results of serologic and pathogenic studies.

Chemical Studies in Delirium Tremens.—Cohn studied the blood constituents of 15 male patients with delirium tremens on admission and after recovery. Treatment varied, but generally it consisted in giving sodium chloride, fluids, thiamine hydrochloride and nicotinic acid orally or parenterally. On admission the serum chloride and carbon dioxide combining power were below normal in nearly all patients. Determinations of total base and available fluid showed low or low normal values. Hemoglobin and serum protein concentrations and the hematocrit values were increased. In the spinal fluid the amount

of chloride was decreased and that of protein increased. On recovery of the patient the concentrations of the substances studied returned to normal, with the occasional exception of the concentration of the serum chloride. All but 1 patient recovered; this patient died within twenty-four hours of admission from lobar pneumonia. Recovery was accompanied by a restoration of body fluids and electrolytes to normal composition. Delirium tremens should be treated by methods which restore fluid and salt to the body.

Cutaneous Reactions to Specific Soluble Substance.—Meyer and Carey used injections of pneumococcus capsular carbohydrate, that is the Francis test, for determining the need of serum therapy in 42 infants and children with typed pneumococcus pneumonia. The results of the test, they say, confirm

its value for controlling the dose of serum in infants and children. However, in their experience the results of the test after chemotherapy with sulfapyridine or sulfathiazole have been irregular and unpredictable. When patients were first treated with serum it was observed that when the result of the Francis test became positive the areas that had been previously injected with specific soluble substance and showed negative results showed typical erythema and wheal reactions after the last dose of serum. Thereafter only one cutaneous test was administered before any serum was given, and the area was observed after each dose of serum. Typical reactions, when they occurred, were usually seen five to fifteen minutes after serum had been administered. It was observed that if single doses of serum were limited to 5 cc. fewer reactions (fever and chills) occurred. In the later cases when the result of the Francis test became positive administration of serum was discontinued. Much smaller amounts of serum were therefore used, with apparently comparable therapeutic effects. The positive reaction is probably due to a local union of antigen and antibody. The time and the intensity of cutaneous reactions varied greatly in the patients given only chemotherapy, but in the patients given serum strong reactions developed and persisted throughout their stay in the hospital.

Effect of Honey on Calcium Retention.—Knott and his associates determined the effect that feeding corn syrup and honey in milk formulas had on the retention of calcium in infants. They found that the average retention of calcium was always higher if honey was included in the formula. The increased retention occurred with both low and high intakes of vitamin D and regardless of the type of milk fed or whether or not lactic acid was used. Further analysis shows that while the favorable influence of honey occurred regardless of other operative factors its magnitude tended to decrease as other beneficial factors were employed. This is to be expected, as each infant has an upper level of optimal response. But despite these factors the use of honey could still improve calcium retention. In view of the results the authors conclude that honey is a carbohydrate which is well suited to the needs of the infant and therefore probably deserves wider use in infant dietaries.

New Classification of Pulmonary Tuberculosis. D. Salkin and A. V. Cadden, Hopemont, W. Va.—p. 126.

Surgery in Pulmonary Tuberculosis.—Adams and Dufault review the results following thoracoplasty on 241 consecutive patients submitted to operation during thirteen years. The last patient was operated on at least two years ago. Among the group considered there were 22 with tuberculous and mixed empyema. Of the entire group 144 were apparently cured. The tuberculosis of 11 was arrested, of 2 was apparently arrested, of 27 was quiescent, of 10 was unimproved and of 1 it was worse. The status of 8 is unknown, and of the 33 patients who died 28 did so from tuberculosis, 7 from empyema and 3 from a nontuberculous disease. Twelve with empyema were cured, 1 improved, 2 were worse or unimproved and 7 died.

Thoracoplasty for Tuberculosis.—According to Skinner and his associates, 226 patients had thoracoplasty between 1924 and 1941; 100 had it by the end of 1935. Of 50 operated on before 1933 24 are apparently still cured in 1941, 5 are improved, 2 are unimproved and 19 are dead. Of the 50 operated on during 1933, 1934 and 1935 30 are apparently cured in 1941, 2 are improved, 5 are unimproved and 13 are dead. Only a preliminary report is possible for the 126 patients operated on since 1935, but up to date 58 are apparently cured, 43 are improved, 17 have unsatisfactory results and 8 are dead.

Surgical Treatment of Hypertension.—Heuer and Glenn studied the results of operative procedures (19 anterior root sections, 12 supradiaphragmatic splanchnicotomies and 18 splanchnic resections with interruption of the first and second

lumbar ganglions) on 49 hypertensive patients. Such therapy is indicated because (1) a lowering of blood pressure has followed the operative procedures, (2) changes in the fundi have occurred and in many cases persisted, (3) headaches have been relieved for variable periods, (4) nervousness has been diminished and (5) early fatigue has been lessened. Twenty-six of the patients are alive from two months to six years and nine months after operation.

*Encephalopathia Saturnina: Report of Case. J. Santillan, F. S. Soriano, Manila, and J. S. Ongjoco, Pasay.—p. 455.

Encephalopathia Saturnina.—Santillan and his associates believe that they are apparently reporting the first case of encephalopathia saturnina to occur in the Philippines. The patient started working in a large printing establishment in 1909. During the time of his connection with the firm he was always in contact with lead. He remembers that about two years after he was employed he began to have periodic attacks of dizziness and headache. He recalls two attacks of abdominal colic. After nineteen years of continuous work he had a sudden and severe convulsive attack. This attack was followed by loss of consciousness, and immediately after it he was unable to

talk or walk. He was obliged to stop working. Gradually, while at home, he recovered his speech, but even after twelve years without contact with lead he has never regained the full use of his right upper and lower extremities. The symptoms coincide with those described by Tanquerel des Planches and Westphal in lead encephalopathy of the apoplectic form. Lead poisoning, like all other occupational diseases, is compensable. The patient was given compensation for total and permanent disability.

Subconvulsive Reaction to Electric Shock.—Watkins and his associates point out that a volunteer, a physician of 25, was submitted to an electric subconvulsive shock. His behavior and experience during recovery were similar to those observed in patients with mental disease after convulsive shocks. The principal features of the volunteer's behavior were absence of somatic and mental complaints, amnesia and disorientation.

Dermatitis from Cutting Oils.—Schwartz points out that soluble and insoluble cutting oils and greases used for lubricating and preserving the temper of cutting tools are the most frequent causes of dermatitis among machinists and metal workers. All petroleum oils have a defatting action on the skin. Consequently a greasy skin with active sebaceous glands is less apt to be defatted than a dry skin. The comedos, folliculitis and boils caused by cutting oils and greases can be successfully treated and prevented by a daily change of work clothes and frequent washing of the affected parts. Pus should be evacuated surgically, and the judicious use of compresses of solutions of boric acid, mercury bichloride 1:1,000 or potassium permanganate 1:2,000 will usually clear up the condition. The allergic types of cutting oil dermatitis are best treated by removing the affected workers from contact with the offending agents. Antiseptic lotions should be used for the moist types; ointments for the dry chronic types; dressings of boric acid, Burow's solution or mercury bichloride 1:1,000 for the acute moist types, and boric acid ointment, zinc ointment, Lassar's paste and coal tar preparations for the dry or dry eczematoid types of dermatitis. Workers with dry, defatted hands should apply a vegetable or animal fat ointment before and after work.

Urinary Content of Lead and Arsenic of Unexposed Persons.—Webster determined the urinary lead and arsenic concentration of the morning specimens of 46 persons (28 adults and 18 children) with no known exposure to lead arsenate. A wide concentration range was found. However, there was no uniformity among the different members of a given family. There was a close correspondence between specific gravity and phosphate concentration. Comparison of these lead and arsenic values with those of men and women living in an apple-growing locality with potential exposure to lead arsenate from the ingestion of apples having the residue from lead arsenate spray on their surfaces and/or from inhalation of lead arsenate dust, spray or particulate matter revealed about the same average values, but the averages were significantly lower for the groups not residing in the apple-growing district. No evidence was discovered to indicate that the urinary lead and arsenic content of children differs from that of adults.

Rat-Bite Fever in Washington, D. C.—Larson reports 3 cases of rat-bite fever observed in Washington, D. C.; from 1 patient *Leptospira morsus muris* and from 2 *Streptobacillus moniliformis* were isolated. The 3 cases furnish the first record of isolation of *L. morsus muris* from a patient in Washington and also the only instances of infection with *Streptobacillus* in the locality. From these cases the author finds that the clinical diagnosis of rat-bite fever may be difficult when certain cardinal features are absent, but this can be offset by employing proper laboratory methods for confirmation.

*Ornithodoros Hermsi and Relapsing Fever in Oregon. G. E. Davis.—p. 2010.

Ornithodoros Hermsi and Relapsing Fever in Oregon.—Davis points out that 2 cases of proved and 3 of suspected relapsing fever have been encountered in central Oregon. He collected 52 specimens of *Ornithodoros hermsi* from a hollow pine log in the immediate area in which the infection occurred. The ticks were tested in seven groups of 5 each and in three groups of 4, 6 and 7 each by allowing them to feed on white mice. Spirochetes were recovered from 6 of 10 test mice. The presence of relatively large numbers of *O. hermsi* in Douglas firs in Colorado and in the pine log in Oregon suggests that dwellings could be infested and that contact with decaying wood used as fuel or for lumber may be a source of infection.

*Rhomboid Depression of Clavicle. S. Shulman, Far Rockaway, N. Y.—p. 489.

Roentgen Therapy for Gas Gangrene.—Kelly and Dowell assemble the data on twelve years of the roentgen treatment of gas gangrene. The decrease in mortality, they say, indicates that with irradiation the disease need no longer be considered serious. Two of their first 8 patients so treated died, but of 364 patients from all sources who were treated during the twelve years (ending with May 1940) with one or more roent-

gen treatments, 42 died, a mortality of 11.5 per cent. The mortality for 288 of the 364 patients given three or more treatments was 5.9 per cent. The diagnosis of the disease in 93 was based on clinical grounds, in 41 on clinical grounds and roentgen evidence of gas in the tissues and in 207 on laboratory evidence of *Clostridium welchii*, and the method of diagnosis for the remaining 23 was not stated. The number of deaths in these four groups was, respectively, 16, 7, 18 and 1. From an analysis of the data the authors conclude that the roentgen treatment of gas gangrene has a direct effect in preventing and curing the infection, and that (1) the administration of serum appears unnecessary, (2) irradiation is effective after serum therapy fails, (3) giving serum may even be harmful to the diabetic patient in whom gas gangrene develops, (4) giving serum may be harmful to aged patients and (5) roentgen therapy of gas gangrene has completely eliminated the necessity of extensive surgical intervention. Amputation and extensive débridement are seldom necessary. They should never be necessary if proper treatment is started early. The study stresses the need for the general use of roentgen therapy for inflammatory disease at the bedside, with an apparatus of adequate kilovoltage. Acute spreading peritonitis has been successfully treated by irradiation. Sulfanilamide should not be used during the roentgen treatment of acute inflammatory processes. The curative action of the roentgen rays is apparently due to the rays' nonspecific antitoxic effect. This antitoxic effect, resembling the nonspecific effect in preventing peritonitis after colonic and rectal operations, was first reported by the Ford Hospital group.

Gas Gangrene in Dogs.—Dowdy and Sewell produced a syndrome comparable to that of *Clostridium welchii* disease in man in 66 dogs. Irradiation had some therapeutic effect in combating the infection in 25 dogs as compared with 25 controls. The survival rates were 36 and 20 per cent, respectively. Preliminary studies on the effect of the time of treatment, the amount of treatment, the size of the dose and the kilovoltage show that they all have a bearing on the survival rate.

Rhomboid Depression of Clavicle.—Shulman calls attention to a normal anatomic landmark of the clavicle which ordinarily is not visible on the roentgenogram but which occasionally may be so well developed as to simulate destructive lesions of bone. It is important to differentiate such an anomaly from the various pathologic conditions (osteomyelitis, tuberculosis, syphilis and malignant neoplasms) known to involve the region of the clavicle. A comprehensive survey of the American literature disclosed only a single reference to the possible occurrence of this anomaly. Occasionally the rhomboid depression may be extremely deep and penetrate about halfway through the thickness of the clavicle. The outline of the upper margin of the defect is usually irregular, and its density is slightly increased. Under such conditions, the anomalous development of the depression appears as a large osseous defect and may easily be mistaken for a destructive process.

Uterine Fibroids with Pregnancy.—From a study of one hundred and forty-four labors among 118 women with uterine fibromyoma whom Thompson encountered among two thousand consecutive private deliveries he concludes that fibroids do not negate pregnancy or nullify the chance of viable infants. The history (previous pregnancies, abortions, labors, menstruation and symptoms) seems the most important indicator, with the size of the fibroids a close second: The better the history the better the course, and the larger the fibroid the poorer the course. There was an increased incidence (10.8 per cent) of premature rupture of the membranes, premature labor, placenta previa, breech presentation and hemorrhage during pregnancy and labor and immediately post partum among the 118 women. Pain and tenderness during pregnancy indicated trouble. However, the trouble was grave in only a few women, and it was usually heralded and never calamitous or catastrophic for the mother. Therefore it seems that without the most serious deliberation a woman should never be informed that pregnancy is impossible because of fibroids and that a miscarriage (which occurred in only 6 among the group) will occur or that much trouble awaits her if she becomes pregnant. Likewise the removal of the uterus with the fibroids should never be urged or suggested—especially in a woman who desires children. The woman should be encouraged to keep her troublesome organ so that it may fulfil its physiologic function.

Ischiofemoral Arthrodesis.—Brittain used ischiofemoral arthrodesis for 35 patients with tuberculosis, osteoarthritis or infective arthritis of the hip. Ischiofemoral arthrodesis afforded a high percentage of fusions in his patients. The operation can be offered any patient less than 65, provided that in tuberculosis the disease does not extend down into the ischium. Ischiofemoral arthrodesis is fusion between the ischium and the shaft of the femur in the region of the small trochanter. The operation consists in performing a subtrochanteric osteotomy at a previously selected site, passing the osteotome into the ischium in the same line for 1 inch (2.5 cm) and introducing a massive flat tibial bone graft, that is the entire medial surface of the tibia. One end of the graft is well implanted in the ischium and the other between the two fragments of the osteotomy. The limb is then abducted so that the lower fragment comes into contact with the ischium, and thus the graft is supported throughout its entire length. The one possible disadvantage to ischiofemoral arthrodesis, as to the iliofemoral operation, is that the disease may involve the graft. Bony fusion followed the first operation in 80 per cent of the author's patients. For 3 patients the operation had to be repeated; for 1 of these it was performed three times. The results with these 3 patients bring the percentage of fusions to 88. If fusion should not occur because the graft was passed too high into the diseased area, the operation can be repeated.

Dyspepsia in the Army.—Hinds-Howell cared for 804 patients with dyspepsia from October 1939 to December 1940. The symptoms of 80, or only 10 per cent, originated during service in the army; in 13 of the 80 the character of the symp-

toms was neurotic. The symptoms of 47 of the 91 Canadian patients developed after their arrival in England. Six patients were New Zealand soldiers. Of the 707 British patients 391 (55 per cent) presented definite evidence of peptic ulceration. The highest incidence of symptoms of duodenal ulcer was among soldiers between 20 and 30 years of age; the same was true of gastric ulcer, although the curve was flatter. Thirty-five had had an acute hemorrhage, 34 a perforated peptic ulcer and 29 an appendectomy, but the duodenal symptoms were relieved only for about two years. The onset of pain after meals was unreliable as a diagnostic factor. Vomiting, more common in soldiers than in civilians, was almost universal, and usually it was followed by partial or complete relief of symptoms. Men with proved ulcers are unfit for military service, but officers and occasionally noncommissioned officers or other useful men should be retained for home duty if arrangement for a suitable diet can be made.

Bacteriology of Recent Air Raid Wounds.—To determine whether pathogenic bacteria are present in wounds immediately after their infliction Spooner examined material (pieces of external wounds, wound tracks and foreign bodies from thirty-one early air raid wounds) at the first surgical cleansing. Pyogenic cocci were less frequent and coagulase-negative staphylococci, aerobic spore-bearing bacilli and *Clostridium welchii* were more common in recent than in older wounds. No bacteria were found in six wounds. Other bacteria found were *Escherichia coli* in six, diphtheroid bacilli in three, nonhemolytic streptococci in three, *Streptococcus viridans* in two, micrococci in six and other clostridia in one.

Cirroid Aneurysm.—Davies-Colley reports the 6 instances of cirroid aneurysm (only 3 were of the head) that he encountered in the last twenty years. In discussing their probable pathogenesis he states that all cirroid aneurysms are the result of a developmental defect in the formation of the capillary barrier between arteries and veins. Most of them follow an intermediate stage of visible dilatation of the capillaries, the cavernous angioma. Trauma may play the part of an accessory factor in their formation but is never the only cause.

Cirroid Aneurysm of Chest Wall.—The large cirroid aneurysm of the wall of the chest that Eckhoff discusses had feeding vessels around the periphery, and one enormous vessel (not discovered until the third operation) entered from behind through an intercostal space. Whereas surgical measures were finally successful in causing the pulsation to cease, a capillary angioma appeared and spread well beyond the original confines of the aneurysm. Irradiation caused the angioma to regress. After this an ulcerated area appeared which was resistant to all ordinary methods of treatment, including cutaneous grafting, for a long time. This patient had a dense mass of scar tissue between the wall of the chest and the surface of the skin. The two treatments with radium added to the scar tissue. Healing followed excision of the whole ulcerated area, the removal of all scar tissue and the covering of the area with a large razor graft.

Influenza in England.—According to Andrewes and his associates, the outbreak of respiratory disease prevalent in southern England in the spring of 1940 was of the long drawn out rather than of the sharply peaking form, "clinically typical" influenza was relatively infrequent and tracheobronchitis with slow recovery was prevalent. Garglings from patients with a diagnosis of clinical influenza were tested by the intranasal inoculation of ferrets, but no evidence was obtained that that virus was prevalent. None of the garglings produced infection in the ferrets. Although there was no general epidemic of influenza in the winter of 1940-1941, clinical influenza occurred sporadically in London and elsewhere in southern England. Eight of 19 garglings or samples of serum received in January and February from as many patients provided evidence that the disease was influenza A. During the same period a detailed clinical study of the acute respiratory infections occurring in a military hospital in southern England was being made, and although no actual epidemic was observed there was a sharply increased incidence of influenza in January and February. The influenza of many of the patients was similar to that seen in 1937 and 1939. Pathologic investigations revealed that 79 per cent of the local material studied was of virus A influenza. Not one of the specimens from 16 patients from various districts examined during March and April 1941 gave evidence that influenza A was concerned. The 1940-1941 studies have shown that testing serums for neutralizing antibodies is a far more delicate index of infection than the inoculation of ferrets. The amniotic method of chick inoculation has given even poorer results than the inoculation of ferrets.

 Refractory Anemia: I. Clinical and Pathologic Aspects. R. R. Bomford and C. P. Rhoads.—p. 175.
 *Id.: II. Etiology and Treatment. R. R. Bomford and C. P. Rhoads.—p. 235.

Etiology of Refractory Anemia.—Bomford and Rhoads examined the records of 66 patients with refractory anemia in an attempt to evaluate the important etiologic factors. Race, sex, age and family history appeared to have no influence. A possible influence of eunuchism, menstruation and the menopause was noticed in a few instances. The incidence of achlorhydria was below normal. Half the patients were known to have been exposed to aromatic hydrocarbons and 1 to roentgen and radium therapy. Exposure to sunlight, ultraviolet and roentgen irradiation seemed to make the condition of a few patients worse. An increasing macrocytosis usually indicated a spontaneous remission. The results of tests of hepatic function suggested that hepatic impairment may be an important factor in the causation of refractory anemia. The simultaneous excretion of coproporphyrins I and III indicated that the disturbance of pigment metabolism in refractory anemia is similar to that observed in hepatic diseases and certain forms of exogenous poisoning but unlike that in pernicious anemia and hemolytic jaundice. The excretion of fecal urobilinogen was above normal levels in half the patients. The hemolytic substances normally present in the human urine were present in a bound or conjugated form in the urine of patients with refractory anemia. The erythrocytes of these patients were slightly more than normally resistant to lysis by saponin. A possible abnormality in the processes of detoxication was detected. The measure of greatest importance in the treatment of patients with refractory anemia appeared to be the prevention of their exposure to any potentially hemotoxic substances or influences. Blood transfusions and dietary supplements were usually indicated for all patients, and splenectomy, as a last resort, for a few.

*Studies on Japanese Type Epidemic Encephalitis: I. Histopathologic Study. Y. Kitagawa.—p. 95.

*Id.: II. Clinical Observation. Y. Kitagawa.—p. 145.

Japanese Type Encephalitis.—Kitagawa made histologic examination of the brain of 6 and the spinal cord of 5 patients who died of Japanese type epidemic encephalitis, with the following results: The predominating change in the brain in summer encephalitis is the increased accumulation of colloid cells, leading to the formation of colloid nodules and glia proliferation and resulting in the production of areas of softening. These nodules always arise at the point of entry of the virus in the parenchyma of the brain and bear definite relationship not only to the virulence of the virus but to individual constitution, as well as to the degree and extent of immunity. They appear to have special affinity for the midbrain, although they may be found throughout the central nervous system, particularly in the gray matter. These structures form primarily as a defensive process of the nervous system, but secondarily they may represent a means of disposing the necrotic material. The glial proliferation and entanglement may have the identical mechanism in their formation as the colloid nodules, and they may be regarded as a special form of Spielmeyer's pseudo-neuronophages and true neuronophages. Microglia may show progressive changes in all parts of the nervous system, but the changes become stationary when the disease process ceases, while the changes in the oligodendroglia are usually negligible. Proliferation of macroglia practically never occurs in the acute stage of the disease. True neuronophages and perivascular infiltration are also of general distribution, but no special significance can be attached to these elements. Thus the summer encephalitis virus shows varying degrees of affinity to the central nervous system, producing changes in the nature of the blood. Primarily it stimulates the microglia, causing accumulation of colloid material at the point of entry and resulting in the formation of colloid nodules and glial proliferation; when it enters deeper into the parenchyma of the brain it causes changes and necrosis of the tissue. Although histologically summer encephalitis resembles von Economo's lethargic encephalitis, the author expresses the view that distinctive characteristics differentiate the nature and the distribution of the changes produced by these two diseases.

Clinical Observations of Japanese Encephalitis.—Kitagawa further reports his observations on the clinical manifestations of Japanese encephalitis in 26 typical patients, of whom 9 were male and 17 female, ranging in age from 10 to 56 years. The season of the year in which the disease most frequently occurred was the summer (July to September). The onset was acute, with cloudiness of the sensorium appearing within one to eight days, usually after the onset of high fever. The author describes in detail various neurologic signs of the disease, but special emphasis is placed on the state of the cerebrospinal fluid. In 26 cases a total of eighty-six examinations were made of the fluid obtained by lumbar puncture. The pressure varied from 45 to 300 mm., with an average of 196 mm. The reaction was always alkaline and the fluid, with only one exception in which slight turbidity was noted on one occasion, water clear. The globulin tests practically all gave positive results, but no tendency for pellicle formation was noted in any sample. The protein content of the eighty samples examined varied from 0.033 to 0.15 per cent, with an average of 0.075 per cent. The Heine sugar reaction was for the most part normal. The cell count in seventy-six samples revealed an average of 173 cells per cubic millimeter, the number decreasing with the progress of the disease. In 2 instances gram-positive diplococci were cultured. The hospital stay ranged from four to one hundred and seven days, the average being twenty-three days; the average duration of the disease with complete recovery was forty-five days. Relapse occurred in 4 cases, and the residual complications were elevation of temperature, disturbance of sleep, headache, nausea and vomiting and hypersecretion of saliva. Complications were as a rule rare, but empyema, peri-

carditis, pulmonary gangrene, pneumonia and bed sores occasionally followed the disease. The more serious after-effects were paralysis of the limbs, paralysis of the nerve and difficulty in deglutition. As a result of these observations the author concludes that the Japanese type of encephalitis is an entity distinct from the lethargic type, and that it is capable of terminating in parkinsonism.

*Experiences with Chemotherapy in Gonorrheal and Nongonorrheal Urogenital Diseases. T. Yoh.—p. 1307.

Chemotherapy in Urologic Diseases.—Yoh employed sulfanilamide and its derivatives in a number of cases of urologic disease, including 140 of gonorrheal and 56 of nonspecific infections. Administration of massive doses of sulfanilamide in addition to the usual method of treatment definitely accelerated the cure of gonorrheal infection, but some of the complications resulting from gonorrhea failed to respond satisfactorily to this mode of treatment. If the patients with gonorrhea were first treated by the injection of either vaccine or autogenous blood, the subsequent employment of chemotherapy appeared to be more efficacious than it was when no preliminary treatment was instituted. The same beneficial effect was observed when treatment with sulfanilamide and its derivatives was preceded by fever therapy. It was difficult to differentiate the effect of the various sulfanilamide derivatives, but sulfapyridine appeared to be effective when other preparations failed to produce satisfactory results. Of the 32 patients who came to the attention of the author after a course of self medication with sulfanilamide or its derivatives only 1 was found to be cured; all the others still suffered from active disease. The drugs were also found to be effective in genitourinary diseases due to staphylococci and streptococci infections, but diseases due to the colon bacillus and the tubercle bacillus were resistant to chemotherapy. Sulfapyridine produced the greatest number of undesirable symptoms, but cessation of medication usually resulted in prompt disappearance of complicating manifestations. One instance of death due to granulocytopenia following massive doses of a sulfanilamide derivative is recorded.

Specific Therapy of Leprosy in Estonia.—Paldrok observed that the causal organism of leprosy consists of granules that are surrounded by an envelop; five or more are generally in one sheath. The common envelop creates the appearance of a rod which Amauer Hansen had designated as the bacillus of leprosy. Paldrok observed, however, that the multiplication of these rods is not like that of bacilli but that the granules adhere to the wall, then penetrate the envelop and develop into dendritic forms as do fungi. He became convinced that the causal organism of leprosy is not a bacillus but rather a fungus and that this explains why the leprosy organism does not grow in cultures suitable for bacilli. He found also that the granules and the covering differ in their chemical composition. Whereas the granules contain free nucleic acid, the envelop contains nucleoproteins. Searching for a substance that would destroy the covering so that the granules could be

reached, he decided to utilize the action of cold in the form of solid carbon dioxide. Rods of solid carbon dioxide are pressed against the leproma for three to four seconds. Lepromas of millet seed size completely disappear about three weeks after the freezing, but with larger ones the freezing must be repeated. At each session fifteen to twenty lepromas are frozen, and the procedure is repeated every two weeks. After four months, the treatment is interrupted for the same length of time. The decomposition products released during freezing are absorbed by the organism and cause the formation of antibodies. There are indications that the solid carbon dioxide treatment is an autoimmunization. The favorable effect of solid carbon dioxide on leprosy has been corroborated by investigators of many different countries. If after two years of treatment with solid carbon dioxide the organism has lost its responsiveness to the substance a new chemotherapeutic stimulus must be employed, and the author found the organic gold preparation solganal effective. In the course of treatment with solganal the organism regains its responsiveness to solid carbon dioxide, so that the two treatments can be used alternately. Good food, a hygienic mode of life, adequate exercise and weekly sweat baths are complementary measures. Those who are apparently cured are kept in the leprosarium for an additional two years. For the first five years after discharge the patients must submit to control examinations every six months. After pointing out that nonspecific shock therapy has largely failed in leprosy, the author says that the efficacy of the solid carbon dioxide and gold (solganal) treatment is proved by the fact that, whereas in 1920 the total number of patients with leprosy in Estonia was 316, by 1940 there were only 113.

Macrocytic Hyperchromic Anemia Without Gastric Achylia.—According to Nielsen it is now generally agreed that gestational pernicious anemia differs from cryptogenic pernicious anemia. Patients with the former often have free hydrochloric acid, have no organic nervous symptoms, seldom show an increased icterus index and do not require continuous liver therapy. In this report a brief survey is given of previous views concerning pernicious anemia with the gastric secretion of hydrochloric acid preserved and the pernicious anemia of pregnancy, with special reference to the cause and the relation to cryptogenic pernicious anemia. Histories are given of 2 cases of pernicious anemia of pregnancy and 2 cases of pernicious anemia with the gastric secretion of hydrochloric acid preserved. Therapeutically the diseases differ from cryptogenic pernicious anemia by their failure to respond to the injection of liver and stomach preparations. On the other hand, they respond favorably to oral administration of liver extract. The author advances the hypothesis that the cause is the same in the reported cases of pernicious anemia of pregnancy and pernicious anemia with preserved hydrochloric acid secretion, namely that the anemia is due to lack of a new antianemic factor. The diseases are taken to be essentially different from cryptogenic pernicious anemia but closely related to Israels and Wilkinson's achrestic anemia, and to tropical macrocytic anemia.

 *Results of Roentgen Treatment of Spondylitis Rhizomelica (Spondylarthritis Ankylopoietica). J. van Ebbenhorst Tengbergen and H. J. N. Dekkers.—p. 522.

Large Niches in Stomach.—According to Myhre a giant niche of the stomach always provokes a strong suspicion of cancer, because it is often stated that niches measuring more than 2.5 cm. in diameter are nearly always malignant. To

throw more light on this problem, the author investigated 23 cases in which large niches had been photographed and in which operation was done. He included in this study all niches with an aperture of more than 2.5 cm., provided infiltration of the wall of the stomach outside the swollen edge of the niche did not clearly prove it to be a cancer. It was found that nine of the twenty-three craters were cancers, while the other fourteen were benign ulcers. Of the fourteen benign niches one measured 2.5 cm. in the roentgenogram, another 6.5 cm. and the others between 3 and 4.5 cm. Of the nine malignant ones one measured 2.5 cm. and the others between 3 and 4.5 cm. The surgically removed specimens usually had a smaller diameter than did the niche on the roentgenogram. Owing to divergence of rays, roentgenograms produce a magnification of 10 to 15 per cent. The author concludes that if no definite sign of cancer can be seen in the roentgenogram the large niches with an aperture of 3 cm. and more can be taken to represent benign ulcers at least as often as malignant ones, perhaps even more often. However, some really are malignant and the differential diagnosis may be impossible, because a roentgenologic improvement during dietetic treatment may prove misleading.

Epituberculosis and Pulmonary Atelectasis.—Westermark says that in 1920 Eliasberg and Neuland described a pathologic condition in tuberculous children which they designated epituberculosis. It is characterized by massive pulmonary consolidations. The roentgenologic aspects are similar to those of tuberculous pneumonia. Three different explanations have been given for the epituberculous opacity: 1. Tuberculous parenchymatous infiltrations are the cause of the opacity. 2. It is wholly or partly caused by obstructive atelectasis. 3. The opacity is caused by a focal reaction as a result of excessive sensitiveness. Reviewing the literature, the author found 44 cases of so-called epituberculosis and observed that among them two different types of changes could be differentiated. A group of 7 cases presents the aspects of a more or less extensive obstructive atelectasis, which is caused by enlarged hilar glands which infiltrate and compress the bronchus leading to the dense region. The opaque lobe occupies a smaller volume than it would normally. There is retraction of the thoracic wall over the opaque lobe and displacement of the heart and the mediastinum to the diseased side. The author describes a case of his own observation and reviews some cases from the literature. In the other condition, the opaque lobe is of normal or larger than normal volume; there is no retraction of the thoracic wall and no displacement of the heart and the mediastinum to the diseased side, but occasionally there is displacement to the healthy side. This process seems to tally with the true form of epituberculosis according to Eliasberg and Neuland. It is caused by a proliferative tuberculosis.

Roentgen Treatment of Rheumatoid Arthritis of Spine.—According to van Ebbenhorst Tengbergen and Dekkers roentgen treatment has been employed in rheumatoid arthritis of the spine (rhizomelic) for the last ten or twelve years. Since most investigators who tried this form of treatment obtained favorable results, particularly with regard to a reduction in pain, the authors likewise resorted to it. In the 27 patients on whom they employed roentgen treatment the diagnosis was well established. The majority had had their complaint for a long time, because the diagnosis is often made rather late. Before roentgen treatment was begun some form of physical therapy had been used on all patients. Some had received injections of the Warren-Crowe vaccine, mostly without much beneficial effect. The authors outline the technical details of the roentgen therapy. The best effects were obtained in the patients in whom the symptoms had existed for only a comparatively short time (less than one year). Summarizing the results of therapy the authors state that 16 patients showed considerable and 2 moderate subjective improvement; 15 were able to continue their daily work. The function of the spinal column was improved in only 4 of the patients. The sedimentation rate decreased in 18 cases. If the sedimentation speed is regarded as an index of the activity of the process, it may be said that in 18 cases the activity was subdued. The authors think that on the whole the results may be designated as favorable.

Book Notices

The Modern Treatment of Syphilis. By Joseph Earle Moore, M.D., Associate Professor of Medicine, The Johns Hopkins University, Baltimore. With the collaboration of Jarold E. Kemp, M.D., Associate in Venereal Diseases, The Johns Hopkins University, et al. Second edition. Cloth. Price, \$7. Pp. 674, with 98 illustrations. Springfield, Illinois & Baltimore: Charles C. Thomas, 1941.

There are many changes in this edition. As the preface states, twenty-three of the thirty-two chapters of the first edition have been completely rewritten. Moreover, the material on infectiousness in syphilis has been greatly amplified, particularly in its relation to treatment. There is a new chapter on public health aspects of syphilis and a much needed chapter devoted to the subject of intensive arsenotherapy. The chapter on interpretation of serologic tests in the diagnosis and treatment of syphilis has been completely rewritten by Dr. Harry Eagle and adds much to the value of the book. Dr. Paul Padgett has revised the chapter on cardiovascular syphilis and Dr. Mary Goodwin has completely revised the chapters on the treatment of the syphilitic pregnant woman and on the antepartum prevention of congenital syphilis, as well as on the treatment of congenital syphilis. As Dr. Moore well puts it, Dr. Jarold Kemp, only recently deceased, a clinician, immunologist and syphilologist of the highest ability, assisted greatly in the complete revision of the entire manuscript.

The reviewer has noted only a few minor items to which exception might be taken. On page 136 the advice is given that biliposol, a liposoluble compound, be given two or three times a week. It is true that on page 141 its use is more properly advised every five to seven days. Again, thiobismol is recommended as an antisyphilitic injection twice weekly. It should be administered more properly three times a week, and because of its rapid excretion there is a question whether this drug should ever be used as an antisyphilitic agent. On page 190, last paragraph, the word "gland" is improperly employed for "lymph node." On the same page the use of B. hemophilus Ducrey vaccine for the treatment of chancroidal infection is not even mentioned, yet it is very useful for syphilitic patients getting arsenical therapy when one might hesitate to use sulfonamide derivatives internally.

Moore feels, page 247, that, for syphilitic patients undergoing treatment with bismuth and arsenic compounds examination of the urine once in two to three months is sufficient. The reviewer thinks that a more conservative period would be once a month. On pages 269 and 278, in late latent syphilis and in benign late syphilis, osseous and mucocutaneous, the advice is given to start therapy with an arsenical. Would it not be better to institute first a course of bismuth compounds? After all, modern methods of diagnosis are not entirely able to detect certain submerged syphilitic changes in the aorta and liver. The reviewer thinks that the first lumbar puncture should be done earlier in the course of the disease rather than at six months. There is difference of opinion, however (page 349). Otherwise, certain persons with early central nervous system involvement will not have their lesions detected.

On page 386, figure 72, the word "thiobismol" is misspelled and the addendum should be "from Cole, Schwartz et al."

But these are only minor items in what is an admirable presentation of the treatment of syphilis. The entire subject is so well handled that it is difficult to pick out exceptional chapters, though the portions on infectiousness, on central nervous system syphilis and on interpretation of serologic tests are particularly well handled. The book will be a "required" standard for every hospital, syphilis clinic and physician and student of syphilis. The authors are to be congratulated for their comprehensive treatment of such an important and almost endless branch of medicine.

The volume is replete with tables and charts to illustrate better the subjects under discussion. Moreover, the printer and the bookbinder have done their work well.

What a pity it is that Kemp is not here to enjoy the deserved encomiums due its authors.

El factor emocional en la etiopatogenia de la enfermedad de Basedow. El mecanismo causal analizado en 24 casos: Conclusiones, patogenicas, terapeuticas, pronosticas y profilacticas. Por el Dr. Leonardo C. Perrusi, adscrito a la Cátedra de clinica médica de la Facultad de ciencias, médicas de Buenos Aires. Paper. Pp. 190. Buenos Aires: "El Atenco," 1939.

In this book the author has made careful and detailed psychoanalytic studies of a group of 24 selected cases of hyperthyroidism and in each instance he finds some psychic trauma responsible for the initiation of the disease. For example, each chapter contains the report of a case of hyperthyroidism, and the titles run as follows:

Chapter II. Basedow's Disease of Psychogenic Origin, Brought About by a Sudden Fear.

Chapter III. Basedow's Disease Aroused by an Inferiority Complex and by Exaggerated Ambitions and Libido.

Chapter IV. Psychogenic Basedow's Provoked by an Insolvable Family Situation.

Chapter V. Basedow's Provoked by Unmanageable Pruritus.

Chapter VI. Basedow's Originated by a Sentimental Drama.

Chapter VII. Basedow's Disease Brought About by Antivenereal Phobia.

Chapter VIII. Basedow's Disease Brought About by the Death of a Relative and a Situation of Desperation.

Chapter IX. Basedow's Brought About by the Prolonged Sickness of the Husband.

After analyzing these and 15 other cases, the author concludes that in almost all cases of hyperthyroidism the disease is produced by emotional factors which excite the gland to hyperactivity via the sympathetic nervous system.

The author feels critical of those physicians who make a diagnosis of hyperthyroidism of unknown origin and states that this diagnosis is incorrect, as the majority of the cases that the author has seen could be classified as dysthyroidism occurring in predisposed persons as a result of emotional disturbances.

The author admits that the factors influencing the predisposition of a patient to acquire hyperthyroidism are poorly understood. Among predisposing factors he lists the degree of civilization, the activity of the patient's life, the geographic position of the country, emotional disturbances, inferiority complexes, conception during a difficult period in the parent's life, and inharmonious function of the endocrine glands.

The author emphasizes that, in addition to the usual treatment of hyperthyroidism by rest, iodine, roentgen rays or surgery, all patients with hyperthyroidism should be subjected to psychoanalytic studies to determine and eradicate the emotional factors responsible for the development of the disease.

There are few who would agree with the author's conclusions as to the etiology of hyperthyroidism. The trend of thought is away from the conception that it is the result of worry, anxiety, fear or any other emotional disturbance. Few would deny that emotional disturbances result in an exacerbation of the symptoms of a patient already suffering from hyperthyroidism, but even fewer would subscribe to the hypothesis that the disease is caused by emotional disturbances. Dr. Perrusi fails to present any new evidence to support the concept of an emotional etiology of hyperthyroidism, nor does he present any logical reasoning in support of such a theory.

His cases, although obviously carefully studied from the psychoanalytic point of view, are not always convincing, and the emotional factors which the author assumes initiated the hyperthyroidism are often far fetched. It would be hard indeed to find any series of 24 cases of any disease in which, if one looked deeply enough into the emotional background of the patient, one could not find emotional factors as significant as those reported in the author's cases.

The book is interesting and carefully worked out from the psychoanalytic standpoint but unconvincing.

Hypoparathyroidism in Denmark: A Clinical Study. By Aage Lachmann. Translated from Danish by Hans Andersen, M.D. Acta medica Scandinavica Supplementum CXXI. Paper. Pp. 269, with 14 illustrations. Copenhagen: Einar Munksgaard, 1941.

Acta medica Scandinavica contains articles pertaining to internal medicine. These articles are published in English, French or German as the authors prefer. The present volume, a clinical study of hypoparathyroidism in Denmark, is printed in English with a summary in Danish and represents work which was begun in 1934. The material has been divided into an introduction, discourses on postoperative hypoparathyroidism, idiopathic hypoparathyroidism, a summary and case records. A

bibliography of three hundred and forty-eight references is included and should be of inestimable value to those interested in the clinical study of hypoparathyroidism. The format is conducive to easy reading, and the descriptions follow in well ordered sequence.

Of special interest is the author's review of the individual symptoms in postoperative hypoparathyroidism. He has divided them into three groups: (1) changes in calcium and phosphorus metabolism, (2) symptoms from the nervous system and (3) trophic changes in the ectodermal tissues. In the study of agents capable of raising the serum calcium level, particular attention is paid to calcium preparations, vitamin D preparations, acidifying remedies, parathyroid hormones, parathyroid transplantations and combinations of the foregoing. Dihydrotachysterol gave the most promising results. For those who are interested in the problem of hypoparathyroidism, this treatise can with little reservation be recommended for correlative reading.

Orbital Tumors: Results Following the Transcranial Operative Attack. By Walter E. Dandy. Cloth. Price, \$5. Pp. 168, with 100 illustrations. New York: Oskar Pfister, 1941.

This is an interesting and instructive presentation of 31 cases of tumors involving the orbit. The 24 cases in which the orbital portion of the tumor was attacked surgically by the transcranial approach again give ample testimony to the surgical skill of the author. In addition to the detailed presentation of the cases there is a discussion of the pathologic nature of the tumors encountered and of the operative procedure. With such wide variations in the microscopic appearance of the lesions described here as Christian-Schüller's disease, one shares the author's reservations regarding the diagnosis of these cases. It is not a little surprising to find the common meningioma referred to here as a "dural endothelioma," a "dural tumor" or a "dural meningioma" when practically every modern pathologist with any considerable experience with these tumors has come to recognize their origin from the leptomeninges. It is rather surprising that two procedures, insertion of a flanged needle into the lateral ventricle for continuous drainage throughout the operation (in addition to opening of the chiasmatic cistern) and the use of motor driven burrs for the removal of markedly thickened bone, which other surgeons have found of great value, have apparently found no place among the surgical procedures of this author. The illustrations, particularly the drawings illustrative of the operative procedures, are excellent and add much to the value of this monograph. Ophthalmologists and neurosurgeons alike will wish to add this book to their libraries.

A Insuficiência coronária (estudo semiológico). Por Calo Benjamin Dias, assistente de Clínica propédeutica médica da Faculdade de medicina da U. M. G. Paper. Pp. 162, with 51 illustrations. Belo Horizonte: Livraria Editora Paulo Blum, 1941.

It is gratifying to have so lucid a review of coronary insufficiency printed in Portuguese. The author has thoroughly reviewed the literature, and a perusal of the monograph shows that he is cognizant of the recent developments in this field. The bibliography of one hundred and sixty-three references covers the American, South American and European literature adequately. The subject is divided into five sections. The first deals with the anatomy and physiology of the coronary vessels, the second with the general concept of coronary insufficiency, the third with its causes and the mechanisms responsible for it, the fourth with the clinical manifestations and the last with the electrocardiographic appearance. The author includes a series of his own cases in the last section. There is little that the physicians of this country can obtain from this monograph not present in excellent reviews on this subject in the English literature.

Alimentación y nutrición en Colombia. Por el Dr. Jorge Bejarano, profesor de higiene de la Facultad de medicina de Bogotá. Paper. Pp. 170. Bogotá: Editorial Cromos, 1941.

This is a good book written by a man who is professor of hygiene at the University of Bogota and president of the Red Cross of Colombia. Dr. Bejarano is concerned over the lack of good judgment in the choice of foods which he finds among so many of the people of Colombia. They take too much sugar and starchy food and do not get enough protein and fat. They take little milk and eggs, and they do not get enough fruit and vegetables. Many persons imbibe altogether too much of the

locally made alcoholic drinks, and they fail to get enough calories in the diet. In most places the water supplies are poorly guarded from contamination with fecal material. Dr. Bejarano has written a book which will give Spanish speaking physicians and intelligent laymen a good idea of the recent advances in the science of alimentation and nutrition. He hopes that more of this knowledge can be put to use in his country.

Analgesia obstétrica: El sueño crepuscular barbitúrico en el parto. Con estudio especial del pentobarbital sódico. Por Juan Leon, profesor adjunto de Clínica obstétrica de la Facultad de ciencias médicas de Buenos Aires. Paper. Pp. 574, with 169 illustrations. Buenos Aires: El Ateneo, 1941.

The author reviews the observations made in a series of 201 patients seen in the obstetric and gynecologic clinic Elísio Cantón of the Medical School of Buenos Aires. In this series pentobarbital sodium was used alone in 80 cases, pentobarbital sodium and scopolamine were used in 40 cases, pentobarbital sodium and paraldehyde were used in 40 cases and pentobarbital sodium and chloral hydrate were used in 50 cases. Leon discusses the effects of these drugs from the standpoint of relief of pain, their effect in shortening or increasing the length of labor, their freedom from aggravation of infections and their effect on the child as far as respiration is concerned. He states that, in relief of pain, success was obtained in 39.6 per cent of cases, that relative failure was obtained in 49 per cent and that failure resulted in 9.5 per cent of cases. No untoward effect was observed with regard to the mother or the infant or in the progress of labor in 76.1 per cent of cases, whereas in 23.9 per cent complications arose. The author believes that, on an average, complete success was obtained in 30.5 per cent of cases. He believes that the drugs which he describes should be used in the first stage of labor but that during the actual birth of the child gas anesthesia or regional anesthesia should be used and that the physician should not use one method of anesthesia as a matter of routine.

Die Nervenkrankheiten des Rindes: Eine Grundlage für eine vergleichende Neurologie von Mensch und Haustier. Von Dr. med. E. Frauchiger und Dr. med. vet. W. Hofmann, ord. Prof. für Rinderheilkunde an der Universität Bern. Cloth. Price, 24 Swiss francs. Pp. 361, with 139 illustrations. Bern: Hans Huber, 1941.

This book on the nervous diseases of cattle and live stock is a real contribution. It is a groundwork for a comparative neurologic study of man and animal. The majority of the illustrations are in relation to cattle. There are two parts to this excellent book. The first part consists of a short abstract of the nervous diseases of the animals together with the clinical anatomy and methods of study. The second portion consists of the diseases of the brain, circumscribed disorders of the brain, diseases of the spinal cord, lesions of the cortices of the central nervous system, peripheral nerve diseases, disturbances of the vegetative nervous system, disorders of the muscles and, lastly, diseases of the nervous system without organic disease (neuroses). There is a good bibliography after each chapter in the two portions of the book. The German is easily read and the statements are clearly written. This book is a most unusual one and is highly recommended to all neuropathologists, neurologists and veterinarians.

Synopsis of Applied Pathological Chemistry. By Jerome E. Andes, M.S., Ph.D., M.D., Director of Department of Health and Medical Advisor, University of Arizona, Tucson, and A. G. Eaton, B.S., M.A., Ph.D., Assistant Professor of Physiology, Louisiana State University School of Medicine, New Orleans. Fabrikoid. Price, \$4. Pp. 428, with 23 illustrations. St. Louis: C. V. Mosby Company, 1941.

In this handy, pocket sized volume are gathered practically all of the well established chemical methods applicable to the study of blood, cerebrospinal fluid and urine. In addition, chapters are devoted to renal, liver and endocrine functional tests and to gastric analysis and basal metabolism. The physiologic and pathologic changes in concentration of the various substances considered are discussed and well charted in relation to clinical findings. Concise statements of procedure, supplemented by references to adequate but less well known methods, render the book of practical value to the intern and the busy physician. The book is not without some minor inaccuracies of statement, and it can hardly be classified as a reference work. In the main, however, it admirably fulfils the authors' purpose by providing a "practical, simple, easily read text on the application of pathologic chemistry to clinical medicine."

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

P WAVE AND CORONARY DISEASE

To the Editor—A man aged 51 had an electrocardiogram made during the course of a general examination, on Dec. 30, 1940. At that time he gave no history or symptoms of heart disease, but the report of the cardiologist was as follows: "Electrocardiogram essentially normal. The negative P waves in leads 2 and 3 are not believed to be of clinical significance." About the middle of July 1941 the man began to complain of such symptoms as dyspnea on exertion and substernal pain on climbing stairs. About the first of August he became ill with an acute bronchitis, and since that time he has noted heart consciousness, dyspnea on exertion and chronic nonproductive cough especially after retiring at night. He has not had typical anginal pain radiating from the arms or up into the neck. An electrocardiogram report on Sept. 26, 1941 states that "P wave changes, including widening, suggest auricular disease—may be functional." The cardiologist further states that "In view of the history and evidence of peripheral arteriosclerosis as shown by moderate thickening of the peripheral arteries and as suggested by electrocardiographic findings, coronary arteriosclerosis is considered to be present. No evidence of cerebral arteriosclerosis (eyegrounds essentially normal)." Another electrocardiogram was made on Oct. 23, 1941 by a different physician, and while the cardiogram appears the same as the one made in September, he states that it is "not definitely abnormal." It is asked that significance of inverted or negative P waves in leads 2 and 3 be explained. Could symptoms as mentioned coming on after the patient had left a quiet occupation for one requiring rather strenuous exertion be a causative factor in producing a coronary sclerosis? In other words, would the cardiogram taken in conjunction with subjective symptoms and with negative findings on physical examination of the heart be indicative of beginning coronary disease? M D, Arkansas

ANSWER—Inversion of P in lead 3 occurs normally, but P inversion in lead 2 is abnormal. The best known changes in the P wave are the broad, tall, notched and upright P waves in leads 1 and 2 which occur in mitral stenosis, and the tall upright P waves in leads 2 and 3 in chronic cor pulmonale. Inversion of P₂ and P₃ usually indicate a change in the direction of spread of the impulse in the auricles. The most common cause is retrograde stimulation of the auricles by a pacemaker located in the auriculoventricular node. This is accompanied by a shortened PR interval (less than 0.12 second). If the PR is not shortened, it is presumed that a sinus rhythm is associated with intra-auricular conduction disturbance. The significance of an inverted P₂ and P₃ depends on the condition giving rise to activity of the subsidiary nodal pacemaker when this is the mechanism of its production or to the cause of the intra-auricular conduction disturbance when the pacemaker is still in the sinus node. Transient P wave inversion is less significant than permanent P wave inversion.

Coronary disease is one of the common causes for P wave inversion in leads 2 and 3, although infectious diseases or excessive digitalis may be responsible in part. Other evidences of abnormalities in the electrocardiogram will help evaluate the meaning of P wave inversion. In short, inversion of P₂ and P₃ is abnormal, but its true meaning must depend on an analysis of the contour of the P wave and its duration, the PR duration, the contour of the ventricular complex and the rate of the heart.

When none of these other factors are altered, too much attention should not be attached to such P wave inversions.

As regards exertion as a causative factor in producing coronary sclerosis, there is no evidence to favor this view other than a philosophical belief that "burning the candle at both ends" leads to more rapid aging of the coronary arteries. It seems more likely in this case to assume that with a more strenuous life the signs of coronary insufficiency become more manifest. The presence of the symptoms in this case are far more significant than the P wave abnormalities, and only by a proper evaluation at the bedside of the circumstances which might give rise to these symptoms can the final judgment be made as to whether or not clinically significant coronary disease is present.

NIH SWABS FOR PINWORMS

To the Editor—Can you give me some information on the NIH cellophane swab frequently mentioned in connection with pinworms? M D, Illinois

ANSWER—The NIH cellophane swab was named by the late Dr Maurice C. Hall, former chief of the Division of Zoology of the National Institute of Health; hence the initials NIH. Hall had found that only approximately 5 per cent of all the

cases of oxyuriasis can be diagnosed from fecal examination. He found from the literature that various types of swabbings and scrapings made from the perianal area provided a much better method of diagnosis. He perfected a simple swab consisting of a glass rod about $\frac{3}{16}$ inch in diameter and 4 inches in length and with a small square or circle of cellophane attached to one end with a small rubber band. The swabbing is made preferably in the morning on the suspected patient before the patient has had his morning stool and before he takes a bath. The skin of the perianal and perineal region is swabbed with the cellophane, and if this is at a home call on the patient it is then placed in a stoppered test tube and taken to the office or clinical laboratory. The cellophane is then removed with a pair of curved forceps, flattened out on a slide in a few drops of distilled water and mounted with a coverglass. Eggs of the seatworm, which will have readily adhered to the cellophane, are therefore easily recognized in the transparent preparation. In order to be absolutely sure that the patient does or does not have oxyuriasis, it is necessary to make a series up to six swabbings, unless, of course, the eggs are previously found. Furthermore, since oxyuriasis is more or less familial, if two or more members of the family are diagnosed as infected it is usually advisable to treat the whole family, including the father.

STRABISMUS IN YOUNG CHILD

To the Editor—Nine weeks ago a boy aged 2 years fell from the steps and struck his head on concrete, landing on the superior lateral portion of the left orbit. He did not become unconscious, and the injury seemed so trivial that a physician was not called. Three weeks later the child went to bed apparently perfectly normal and awakened in the morning with a decided internal squint of the left eye, which to date has shown no signs of improvement. I was consulted on the day the squint occurred. I delivered this child, and the delivery was perfectly normal. The boy's head was roentgenographed, and there were no signs of fracture, although the physician who made the roentgenogram stated that roentgenograms taken at this age frequently are unsatisfactory. I referred the parents to an eye specialist, who believes the condition to be paralysis of the abductors due to the injury, possibly resulting from the formation of a small hematoma, and also states that he feels sure it is not a Gradenigo syndrome. I referred them also to a local neurologist, who states that he believes it to be not the result of an injury but paralysis of the abductors, cause unknown, a condition which occurs in children between the ages of about 2 to 4 years but which may but does not always clear up around the age of 14. I would appreciate information on similar case records of spontaneous or traumatic paralysis of the abductors. Assuming that this is paralysis of the abductors without remission, is there any operation on the eye muscles which will relieve the condition, and if so at what age should this be done so that the sight of the eye will not be impaired? Do you have any other studies to suggest or any treatment? M D, Pennsylvania.

ANSWER—It is impossible to tell in the absence of details of the examination whether the condition is a paralysis or a concomitant strabismus. The injury is an unlikely cause owing to the long interval between it and the onset of the squint (three weeks, in a very young child). It is a common history that strabismus in a child begins abruptly, the early stages being overlooked by the family. Paralysis of the abductors dating from birth is not uncommon. It is decidedly uncommon coming on spontaneously at the age of 2 years. Convergent strabismus coming on at this age is exceedingly common. Paralysis produces diplopia, which might cause the child to hold his head in a position to avoid diplopia (turned toward the right). In paralysis, if the patient is made to fixate first with the normal eye and then with the paralyzed eye, the other eye being covered, the deviation of the normal eye under cover, when the paralyzed eye fixates, is greater than the deviation of the paralyzed eye when the normal eye fixates. In a concomitant strabismus the deviation is approximately equal. Cases of true paralysis tend to become concomitant before long.

In the absence of more data a diagnosis cannot be made. The prognosis for spontaneous recovery is not good. This is true whether the condition is paralytic or not. Care should be taken that the squinting eye does not become amblyopic from disuse (suppression to avoid diplopia). Should signs of this appear, the good eye must be occluded to compel use of the other eye. This is important for several years. If due care is exercised along these lines, operation may be postponed indefinitely without the sight becoming impaired. Operation to straighten the eye gives good results and should be done before the patient acquires an inferiority complex due to consciousness of his defect. The operative treatment is satisfactory. The operation of choice depends on whether there is a total paralysis or a moderate or a slight paresis and should of course be determined by the surgeon to whom the operation is entrusted. Often more than one operation is needed.

CHEMICAL DISINFECTION OF INSTRUMENTS

To the Editor—I am interested in using anhydrous acetone as a sterilizing agent for syringes, knives and instruments. I find that when I use a germicide containing formaldehyde I must rinse the syringes in distilled water before using them. I have been told that acetone can be used instead and that syringes may be taken out of the solution, air dried and used for intravenous work. After lancing pus pockets I usually soak the knives in 70 per cent rubbing alcohol for one hour. Could they then be returned to the acetone solution and used later without further sterilization? Please advise as to whether or not acetone is a satisfactory bactericidal agent. I have also been told that 99 per cent isopropyl alcohol is satisfactory for this purpose, but I find that it takes too long for air drying and leaves a greasy film on the syringe. A chemist suggested to me that a mixture of two thirds acetone and one third isopropyl alcohol would also be suitable for this purpose. Do you know of any other type of anhydrous antiseptic or bactericidal agent which would not rust instruments because of their water content and yet would still sterilize, and from which syringes could be air dried and used for intravenous work? If so would these agents be superior to the acetone or isopropyl alcohol or a mixture of the two?

M.D., New Jersey.

ANSWER—Chemical disinfection of instruments is a problem which has not yet been solved satisfactorily. Spaulding (*Surg., Gynec. & Obst.* 69:738 [Dec.] 1939) tested seven solutions commonly used for "cold sterilization" of instruments and found that, although these agents were able to kill vegetative bacteria within ten minutes, eighteen hours or longer was required by all of them to destroy sporulating organisms. The best results were obtained with formaldehyde-alcohol and borax-formaldehyde solutions, and these preparations also proved to be the least corrosive.

Soaking knives which have been used to lance pus pockets in "70 per cent rubbing alcohol" for one hour is not a method to be recommended, since it is doubtful whether the spores present are killed by such a procedure. Acetone is a relatively weak germicide, even against nonsporulating organisms, and there is no reason to believe that even prolonged submersion in this agent would contribute much to sterilization of contaminated instruments. As far as can be ascertained, the proposed mixture of acetone and isopropyl alcohol has not been investigated for its antibacterial action; but, since neither of the ingredients is very effective against spores when tested independently, one would not expect much from the combination.

The fact is, no single solution has been proposed as yet which combines the virtues of noncorrosiveness, reasonably rapid antibacterial activity and volatility sufficient for practical air drying without residue. Exposure to steam under pressure remains the most reliable and satisfactory method of sterilizing contaminated instruments. If "cold sterilization" is to be used, at least four steps are required: (1) thorough mechanical cleansing of the instruments so as to remove all blood, pus and other foreign material which might harbor bacteria, (2) prolonged soaking in a formaldehyde-alcohol or borax-formaldehyde solution, (3) rinsing with water and (4) drying under sterile conditions. There is no reason why acetone should not be used to facilitate this last step. Syringes and needles dried with acetone can safely be used for intravenous work, provided they are sterile.

LAUGHING AND PETIT MAL

To the Editor—A man aged 26 complains of drowsiness and petit mal attacks brought on by any humorous situation. He loses consciousness momentarily but usually recovers before he falls. Things go black, yet he is aware of his surroundings to some extent. He can control his attacks to a certain extent by refraining from laughing. A distant relative is believed to have reacted similarly. She got relief from thyroid therapy. His neurologic examination is negative. He has ruddy cheeks, weighs 155 pounds (70 Kg.) and is 5 feet 6 inches (168 cm.) tall. The thyroid is normal. He has no other symptoms of thyroid insufficiency. The basal metabolic rate is -20. His temperature averages 97.6 to 98.2 F. The blood pressure is 105 systolic and 60 diastolic. There has been no response at all to 10 grains (0.65 Gm.) of thyroid daily and no ill effects. I have increased it to 16 grains (1 Gm.) daily (Armour's thyroid). Why haven't there been any toxic symptoms? How much thyroid can I give? Do you think this is the wrong therapy? Would you advise amphetamine for the drowsiness and phenytoin for the petit mal? Any advice will be appreciated.

C. L. Feiler, M.D., LaFayette, Calif.

ANSWER—The diagnosis of petit mal should be confirmed by an electroencephalogram. Laboratories for such examinations are now being established in various parts of the country. The literature on petit mal and electroencephalographic records is summarized by W. G. Lennox (*Science and Seizures*, New York: Harper & Brothers, 1941). As Lennox states, "the electrical record of the brain gives the most dependable evidence about the type and severity of the condition, the effect of treatment and the hereditary implications" (p. 93).

Prodromes of various types are frequently found in the period preceding a paroxysm. Gaiety and laughter are among them, and Dostoevsky, the Russian novelist, according to S. A. K. Wilson (*Neurology*, London, Edward Arnold & Co., 1940) had periods of "supreme ecstasy" before attacks. Thyroid treatment is not known to have any effect on petit mal.

Treatment should consist of phenobarbital or phenytoin sodium or both. The combination of these two drugs not infrequently is better than either given by itself. The use of amphetamine is not advised. The dose of phenobarbital and phenytoin sodium is gaged by trial, although if repeated electroencephalograms can be taken at intervals of three months a more exact evaluation of the amount of drug needed to control the attacks can be estimated.

The dose of thyroid is excessive and certainly carries dangerous potentialities. It is always advisable when administering thyroid to check carefully for heart rate, tremor and basal metabolic rate at frequent intervals. Furthermore, thyroid in this instance does not seem indicated.

GENERALIZED RASH AND PREMATURE DELIVERY

To the Editor—A woman aged 34 had three previous pregnancies. During each pregnancy there was a rash with considerable itching all over her body in the fourth month. Each pregnancy terminated prematurely at the beginning of the seventh month. The rash disappeared with the termination of pregnancy. Only one child survived. She is now pregnant again and I should like to prevent the rash and the premature delivery. The previous three deliveries took place out of town and I have only scanty information about them. The physical examination was negative with the exception of an inclination to increased blood pressure (145 systolic, 80 diastolic). The blood Wassermann reaction was negative; the urine examination was negative; the blood count, including a differential count, was normal. The urea nitrogen was within normal limits. The eyegrounds were normal. I have the feeling that we have to deal in this case with an allergic reaction toward some products of pregnancy. Is there any possibility that the patient may be desensitized? Is progesterone indicated in this case?

Joseph Kaschmann, M.D., Hartford, Conn.

ANSWER—The generalized rash which develops late in pregnancy is probably toxic in origin but it may be on an allergic basis. There have been no attempts at desensitizing such a patient, probably because the complication is so rare. Generalized cutaneous eruptions may be on the basis of a neurodermatitis, particularly in high strung, nervous persons. These patients should be treated with sedatives, such as the barbiturates, plenty of rest and a carefully selected diet. Locally, soothing antipruritic lotions usually suffice to give the patient relief.

The premature termination of pregnancy in this case may well be due to a latent vascular-renal disease which is not apparent in the usual examination. Other factors may play a role in such cases. Abnormalities of the reproductive tract or an abnormal endocrine balance occasionally accounts for such a course. The patient should have a basal metabolism test and, if the reading is below normal, thyroid in liberal amounts should be administered throughout the pregnancy. The use of vitamin E in the form of alpha or mixed tocopherols has been advocated. The latter can be given in 40 or 50 mg. capsules two or three times a day during the entire pregnancy. Progesterone is of value if it is administered during the first part of the pregnancy. One mg. parenterally can be given three times a week. Progesterone is likewise available as a salt which is efficacious by the oral route. Some success has been reported in the prolongation of pregnancy by the administration of this material during the last two or three months of the gestation. Unusual stimuli such as coitus, douches or violent exercise should be omitted during the last trimester.

POLLENS IN BRAZIL

To the Editor—In order that I may properly advise a patient who is leaving for Rio de Janeiro, will you please publish what data are available relative to the pollen count in that area?

Allen L. Richardson, M.D., Detroit.

ANSWER—Data have not been published on pollen or fungus spore incidence in the immediate vicinity of Rio de Janeiro. However, daily studies were made at Belo Horizonte, some 175 miles north of Rio de Janeiro, by J. B. Greco, A. Oliveira Lima and A. Tupinambá from January 1940 until July 15, 1941. These investigators found little pollen from trees or weeds of any kind, although small amounts of Western ragweed (*Ambrosia psilostachya*) are present in the area. In their article awaiting publication in the *Journal of Allergy* exact figures are not given, but they note a definite grass season lasting approximately from the middle of May until the middle of June. The pollen at that season is attributed principally to Bermuda grass (*Cynodon dactylon*).

LYMPHOGENOUS (LYMPHATIC) LEUKEMIA

DIAGNOSTIC, PROGNOSTIC AND THERAPEUTIC CON-
SIDERATIONS BASED ON AN ANALYSIS OF ITS
MORPHOLOGIC AND CLINICAL VARIANTS

FRANK H. BETHELL, M.D.

ANN ARBOR, MICH.

Lymphogenous leukemia comprises a group of pathologic states which have as their common attribute disordered and continued proliferation of lymphocyte-forming tissue not limited in response to any recognized irritant or other stimulus and manifested by continuous or intermittent alteration in the lymphocytes of the circulating blood.

Until the possible relations of leukemia to neoplastic, metabolic and infectious diseases have received greater elucidation no classification of the types of lymphogenous leukemia can be wholly satisfactory. The lack of other bases for the differentiation of leukemic lymphogenesis has led to reliance by many authors on clinical criteria, such as the apparent course of the disease and the gross regional involvement. The shortcomings of such a classification as a guide both to prognosis and to therapy are made evident by the study in retrospect of any considerable number of cases.

The application of methods for the differential staining of fixed blood films, supplemented by the oxidase reaction and supravital technics, has made possible recognition of the type of blood cell involved in the leukemic process and its approximate stage of development. Examination of circulating cells, lymph tissue and bone marrow provide grounds for the subdivision of lymphogenous leukemia. In all forms of leukemia pathologic variants of cell structure and behavior are common, but among persons with lymphogenous leukemia a distinct and persistent type of abnormality is not infrequently encountered. Such persons form a class which was first differentiated by Sternberg.¹ He observed the transformation of locally invasive lymphosarcoma into a frankly leukemic process characterized by lymphosarcoma cells in the blood stream.

Important studies descriptive of the structure of the circulating lymphosarcoma cell which serve to separate it distinctly from the lymphoblast, the young lymphocyte and the leukemic lymphocyte have been

published by Wiseman² and by Isaacs.³ In particular the study of blood films made on cover slips surfaced with brilliant cresyl blue and stained after drying with Wright's stain, as recommended by Isaacs, has proved of great value. Stained in this way the lymphosarcoma cell, according to Isaacs,³ possesses

certain differentiating features . . . the most marked being the peculiar characteristics of the nucleolus. This is usually eccentrically placed, single, very rarely multiple. . . the nucleolus stands out as a sky blue, round area, surrounded by a deep, blue black rim of chromatin which is piled up around it. . . In the true immature lymphocyte or lymphoblast, under these conditions, the nucleolus appears as a light blue "hole" or area in the chromatin structure, without the heavily staining rim. The nucleoli are more likely to be multiple in the immature lymphocytes or lymphoblasts than in the lymphosarcoma cell.

The lymphosarcoma cell, in films, varies in size from 7.5 by 9 microns to 12 by 13.5 microns. The nucleus is usually oval or oblong, occasionally being egg shaped (thicker at one end) in films. Kidney shaped or notched forms are common in some specimens. The stained chromatin is coarsely reticular and somewhat spongy in structure and the chromatin around the edge is thickened into a fairly definite nuclear wall, differing in this respect from the monocyte. The cytoplasm of the cell is sparse, deeply basophilic, and with the brilliant cresyl blue, Wright's stain, appears as a fine, blue lace-work.

It therefore becomes possible further to classify patients with lymphogenous leukemia into three main groups on the basis of the type of lymph cell concerned in the process: the lymphoblast, the lymphosarcoma cell and the lymphocyte. Separate consideration of the group with lymphosarcoma cell leukemia clarifies many apparently conflicting observations regarding the age incidence, the clinical course and the response to roentgen therapy of persons with lymphogenous leukemia.

The material of the present study comprises all patients with leukemia observed at the Simpson Memorial Institute from 1928 to 1940 inclusive on whom the recorded data are sufficient to permit reevaluation from a diagnostic standpoint. Blood films made for practically all these patients are on file, and whenever consideration of the original observations led to reasonable doubt regarding the correct classification the films were reexamined. In all, reference was made to the films of 125 patients. The disease of approximately 10 per cent of more than 200 patients originally diagnosed as some form of lymphogenous leukemia was reclassified as myelogenous or monocytic. A few

patients were rejected entirely as having either infectious disease or carcinoma invading the blood stream. The number of persons with leukemia was 434, and of this total the patients with lymphogenous leukemia numbered 190 (43.8 per cent). Included among the latter were many patients who had provided source material for a number of earlier communications (Isaacs,⁴ Rowe⁵ and Friedgood⁶).

There are in this series 52 cases of lymphoblastic, 70 of lymphosarcoma cell and 68 of lymphocytic leukemia. Further subdivision has been made into subleukemic and leukemic states at the time of first observation (table 1). The criteria employed for this purpose are as follows: Subleukemic: At least 10 per cent of the circulating white cells exhibit a specific type of abnormality on which the morphologic diagnosis is based, but the total of such cells does not exceed 10,000 per cubic millimeter. Leukemic: At least 50 per cent of the circulating white cells exhibit the type-specific abnormality, and their total exceeds 10,000 per cubic millimeter. Any realistic consideration of

leukemia requires the relegation of quantitative changes in the circulating blood to a position of subsidiary prominence. Yet it is for patients whose disease is characterized by a leukocyte count within the usual range and by no great divergence from the normal in the distribution of cell types that accurate diagnosis becomes most difficult. All forms of lymphogenous leukemia have been observed to undergo transition from the subleukemic to the leukemic state, and vice versa, but it is in the lymphoblastic and lymphosarcoma cell

types that a subleukemic picture is revealed in the majority of cases at the initial examination. The type of lymphatic hyperplasia referred to as pseudoleukemia was described by Cohnheim before present staining methods were available, and it has been found that in

Fig. 2.—Lymphosarcoma cells from a case of subacute lymphosarcoma cell leukemia.

this disease, which may run an exceedingly chronic and benign course, there is usually a relative lymphocytosis, with at least the periodic appearance of atypical lymphocytes in the blood. Therefore it has seemed justifiable to apply the designation of subleukemia to it and to discard the term pseudoleukemia. With this view Krumbhaar⁷ and Forkner,⁸ among others, expressed agreement.

Pathologic examination when performed substantiated the hematologic diagnosis in all cases included

sented in figure 4. Lymphoblastic leukemia is a cataclysmic disaster of childhood, occurring in the majority of cases in the first decade of life and beginning and terminating in 90 per cent before the age of 20. Two thirds of our patients were male. These data are in substantial agreement with those published by Minot and Isaacs,⁹ Ward,¹⁰ Ramsay,¹¹ Warren,¹² Mills,¹³ Simonson¹⁴ and others.

At any period of life lymph tissue may undergo sarcomatous change, and after a variable interval the neoplastic cells may break through the enclosing connective tissue and circulate freely in the blood stream. Among females no significant predilection for any age is manifest, but among males the incidence of lympho-

somewhat less than that observed by Ward,¹⁰ Minot and Isaacs,⁹ Leavell¹⁷ and Wintrobe and Hasenbush.¹⁶

The earliest evidence of ill health in cases in which the disease subsequently was diagnosed as lymphogenous leukemia and the occurrence of various symptoms during the course of the disease are shown in tables 3 and 4. The most common early manifestations of lymphoblastic leukemia were lassitude, ease of fatigue and weakness, symptoms generally referable to anemia. In contradistinction to the observations of Warren,¹² Pierce¹⁸ and Mills,¹³ infection at the outset was noted relatively infrequently, although during the illness infections of the ears, the upper respiratory tract or the skin were observed in nearly half the cases. With both lymphosarcoma cell and lymphocytic leukemia the most common first sign of disease was enlargement of peripheral lymph nodes or the spleen, usually of the former. Throughout the course of lymphoblastic and lymphosarcoma cell leukemia, anemia, fever, hemorrhage and infection were the most conspicuous features. With the lymphocytic type fever and hemorrhage were noted much less frequently.

The duration of life after the appearance of symptoms in cases in which the date of death is known is presented in tables 5, 6 and 7. Death occurred within four months in 70 per cent of the cases of

sarcoma cell leukemia appears roughly to parallel that of lymphoblastic leukemia in childhood and that of lymphocytic leukemia in mature years. It is of interest that between the ages of 10 and 40 the sexes are affected equally by lymphosarcoma cell leukemia, whereas outside these limits there is a decided predominance of males with the disease. Of the complete series 70 per cent are males.

Lymphocytic leukemia in this series was not found before the fourth decade except in 1 woman who had symptoms of the disease at 28. The age distribution agreed closely with that observed by Rosenthal and Harris¹⁵ and by Wintrobe and Hasenbush.¹⁶ As with the lymphosarcoma cell form women were generally affected at an earlier age than men. Sixty per cent of males were more than 60; whereas 80 per cent of females were less than 60. For the whole group with lymphocytic leukemia the percentage of men was 62,

lymphoblastic leukemia, with an average survival period for the whole group of four months. The duration of lymphosarcoma cell leukemia is extremely variable, but nearly one-half the patients died within one year of

by lymphosarcoma cells. The duration of life in lymphocytic leukemia, although variable, was longer in this series than in others reported in the literature (Minot and Isaacs,⁹ Leavell¹⁷ and Wintrobe and Hasenbush,¹⁶ averaging four and eighty-five-hundredths years. The difference is attributed partly to the careful exclusion

Fig. 4.—Incidence of lymphoblastic, lymphosarcoma cell and lymphocytic leukemia according to sex and age of patient at onset of symptoms

of cases believed to represent lymphosarcoma cell leukemia and in part to efforts by the staff and the social service department to remain informed concerning the status of former patients, thus preventing many with more chronic disease from becoming lost to observation.

When observations were sufficiently frequent to justify classifying the patients according to the quantitative characteristics of the blood picture throughout the course of their illness, the duration of life from the onset of symptoms and from the date of the first observation was considered with reference to subleukemic and leukemic changes (table 8). Decreases of the leukocyte count induced by roentgen therapy were not considered in this classification. In patients with lymphoblastic and lymphosarcoma cell leukemia the

None.....	0	0	0	0	2	2.9

duration of life was appreciably shorter in the presence of a high white cell count, whereas no such difference was observed among patients with lymphocytic leukemia.

The immediate causes of death among 86 patients with lymphogenous leukemia are shown in table 9. The greatest hazard to life in lymphocytic leukemia is the susceptibility to infection, particularly pneumonia, but for patients with this disease, including many elderly persons, there is at least one chance in three of dying of a cause wholly unrelated to leukemia.

Differentiation of lymphogenous leukemia according to the morphologic characteristics of circulating leukemia cells aids in the decision regarding the suitability of roentgen therapy and contributes to the determination of the dose, the number of treatments and the regions of the body to receive treatment. A summary of the results obtained from roentgen therapy is presented in table 10. In the evaluation of data, when more than one course of therapy was employed the most favorable response was selected.

The experience gained from this series is in agreement with that of Stengel and Pancoast,¹⁹ Minot and Isaacs,⁹ Simonson¹⁴ and others in demonstrating the negative and often harmful effects of radiation therapy for lymphoblastic leukemia. Therefore I feel justified in withholding this form of treatment from patients with the disease, even when urged to employ it by their relatives.

In the management of lymphocytic leukemia roentgen therapy has proved of much greater value than the use of arsenicals or any other form of treatment employed.

The usual procedure has involved the use of 200 kilovolts and a dose per treatment of 150 to 200 r measured in air to ports ranging from 10 by 10 to 15 by 15 cm. A series of daily treatments numbering usually eight to twelve is applied regionally to the peripheral lymph node areas, the mediastinum, the retroperitoneal region and the spleen. The indications for therapy are anemia, debility, evidence of increased metabolism, pressure symptoms and, least important, a progressive rise in the leukocyte count. The interval between courses of therapy is made as long as possible. Anemia and thrombocytopenia do not militate against the effectiveness of roentgen therapy in cases of lymphocytic leukemia except as they may be part of the terminal cachexia of the disease. Many patients retain the property of responding to roentgen therapy, given many times over a period of years. It appears that ultimate failure to respond depends not so much on an acquired "refractory" state, brought about by previous therapy, as on the progressive nature of the disease, often characterized by increasing proliferation of young lymphocytes and lymphoblasts.

tory. In patients with lymphosarcoma cell leukemia an exceedingly rapid decrease in the white cell count after irradiation is common and there may be associated

SUMMARY AND CONCLUSIONS

A series of 190 cases of lymphogenous leukemia subdivided into cases of lymphoblastic, lymphosarcoma cell and lymphocytic leukemia on the basis of the morphologic characteristics of the pathologic lymph cells in the circulating blood, is analyzed with respect to age and sex incidence, symptoms, duration of life and response to therapy.

Lymphoblastic leukemia is a disease of childhood, affecting twice as many males as females and characterized by anemia, fever, a tendency to uncontrollable hemorrhage and susceptibility to infection. Its duration is usually less than four months, and its course in most cases is either uninfluenced or adversely affected by ioentgen therapy.

Lymphosarcoma cell leukemia is a distinct morphologic and clinical entity, characterized by the presence

severe toxic symptoms. Localized therapy directed only toward the relief of pressure manifestations is often advisable for such patients, but some derive prolonged benefit from roentgen therapy to all of the major regions of lymphatic tissue.

Other means of treatment which have been used with some success on a few patients with lymphocytic or lymphosarcoma cell leukemia include liver preparations administered orally and parenterally, compound solution of iodine (Lugol's solution) and solution of potassium arsenite (Fowler's solution), the last-mentioned remedy in doses gradually increasing to 30 minims (1.8 cc.) administered daily or until toxic effects are observed. In the treatment of lymphoblastic leukemia symptomatic relief is all that is attempted and reliance is placed chiefly on blood transfusion, which in some cases results in transient reduction of activity of the leukemic process

of lymphosarcoma cells in the blood stream. Males are predominantly affected, and the disease may occur at any age. After the development of a leukemic blood picture the course is usually rapid, but in some cases roentgen therapy cautiously employed exerts a noticeably beneficial effect.

Lymphocytic leukemia affects more males than females and occurs almost exclusively in the middle and later years of life. Its course may be relatively benign and is usually favorably influenced by roentgen therapy.

The prognosis and therapeutic indications cannot safely be based solely on morphologic characteristics of the affected cells, but the histologic condition of the blood and the blood-forming organs as a whole, considered in conjunction with the clinical features, provides a basis for a plan of treatment and a reasonably accurate prediction of the course of the disease.

LYMPHATIC LEUKEMIA

IMPORTANT FACTS ADDITIVE TO ITS CLINICAL
AND HEMATOLOGIC RECOGNITION

B. K. WISEMAN, M.D.

COLUMBUS, OHIO

Progress in medicine always has depended primarily on the solution of the basic problem of the mechanism of the production of disease. In some fields, as for example that of infectious diseases, the basic factors are known in quantity sufficient to provide diagnosis and treatment on a plane of efficiency which removes many of them from a position of threat to longevity. In other fields, however, so few of these factors are known that any attempt to reconstruct the mechanism of these diseases can result in nothing more acceptable than a working hypothesis, with all the limitations that this implies. Nevertheless, such working hypotheses, provided that they are founded on facts, even if there are few, are fundamentally important in laying a foundation on which construction, and in certain details perhaps reconstruction, may lead to a universally acceptable account of the mechanism of the disease. Additionally, of immediate practical value, a system of thought the elements of which do not violate the facts observed in the clinic and laboratory aids materially in the recognition, treatment and prognosis of the disease.

Specifically, these principles have been applied to the problem of the primary diseases of the lymphatic tissues. The present paper summarizes in broad perspective a working hypothesis applicable to a sounder understanding of these dyscrasias as seen in the clinic. It is important to add that whatever shortcomings in this hypothesis may be revealed by future investigations, the theory works in the clinic and makes possible exact identification, better treatment and a more reasonable prognosis than was hitherto possible. Because this hypothesis works in practice, it is not felt that this fact, obversely stated, detracts from the possible soundness of the theory.

NOMENCLATURE

From any point of view, the terms lymphoma and lymphoblastoma to designate any of the primary diseases of the lymphoid tissues do not appear desirable. The use of either serves (1) to deny that there is any virtue in trying to determine the mechanism of the production of the several types of lymphoid diseases, (2) to deny that there is any fundamental difference between them or (3) to constitute *prima facie* evidence of the technical inability of the diagnostician (or pathologist) to differentiate between them. Of these three inferences, the latter is the only one that might be acceptable. When so used, the diagnosis should be construed by the interested parties on this basis and not in a sense that further dissection of the exact nature of the process is futile and of no theoretical or practical value. For example, a case of lobar pneumonia might be labeled as one of "infectious disease" rather than

"lobar pneumonia, pneumococcus type I." The charge is made here that this use of the term, while not essentially incorrect, is too broad and conveys too little.¹

A final statement on the nomenclature of the lymphatic diseases includes the fact that while descriptive pathology may justify a variety of terms, a thorough study of the clinical diseases in this category indicates that the terms lymphosarcoma, leukosarcoma and lymphatic leukemia (including the type of Cohnheim) are accurate and adequate to embrace all the now known types of noninfectious primary lymphocyte dyscrasias. Lymphatic leukemia without lymphemia is of course a contradiction unless one defines the term leukemia as a disease entity without the original implication of leukemia meaning "white blood."

MECHANISM OF PRODUCTION OF THE PRIMARY
LYMPHATIC DISEASES

A survey of the known facts concerning the growth characteristics of cells shows that multiplication of these elements is determined by two, and only two, factors, namely maturation and division. Abnormalities in the growth of cells therefore theoretically must be modification in the participation of these two factors acting singly or together. It is therefore possible to construct a list of the theoretically possible lymphoid diseases and compare these with the forms of lymphoid diseases actually observed in the clinic. A diagrammatic representation of this relationship is shown in figure 2. In the center of the circle the origin of the lymphocyte is shown from the reticular cell, the definitive circulating cell achieving its mature form through successive stages of maturation and division. Normally maturation and division occur simultaneously; if either is interfered with, diseases primarily involving the lymphocyte are theoretically possible.

As shown in figure 2, this works out theoretically to give three types of hyperplasia—one with normal lymphocytes and two with immature lymphocytes, the cells of both showing defects in maturation but only one showing neoplastic features. The placing of the diseases in this figure corresponding with the mechanism that is suggested as at fault results from a detailed study of the clinical entities named, all available criteria being applied which have come into my possession from ten years of study in this field. Briefly stated, when the lymphocytes produced in the course of the several types of primary lymphatic diseases are assayed for evidences of maturation with the criteria previously published,¹⁰ it is found that maturation proceeds according to and parallel with the numerical fluctuations in the lymphocytes (in consonance with the speed of production) only in the lymphopoiesis of the known infectious states (fig. 3¹¹). The lymphocytes in chronic lymphatic leukemia do not show abundant maturative phenomena when large numbers of cells are being produced (fig. 4¹²). Neither do they possess certain features regularly seen in neoplasia in general. On the other hand, the lymphocytes in cases of acute lymphatic leukemia and of lymphosarcoma, either with or without

From the Department of Medicine, Ohio State University College of Medicine. Supported in part by a grant from the Cowley Fund.

Read before the Section on Practice of Medicine at the Ninety-Second Annual Session of the American Medical Association, Cleveland, June 4, 1941.

Because of lack of space, this article is abbreviated in THE JOURNAL by the omission of some illustrations, tables and text. The complete article appears in the author's reprints.

leukemic blood (leukosarcoma), while also not showing the maturative phenomena expected, do possess all the attributes of neoplastic cells. On the basis of these observations, therefore, it would appear that figure 2 should be completed as shown.

TABLE 4.—First Mechanism of Production of Lymphatic Leukemia

Localized Origin (neoplastic)	
Without Lymphemia (lymphosarcoma)	With Lymphemia (acute lymphatic leukemia "leukosarcoma")
Facts in Support of Neoplastic Mechanism	
1. Acute course < 1 year	
2. Two types of lymphocytes	
3. Frank metastasis observed in lymph nodes	
4. Mitosis > 5/1,000; average 18/1,000	
5. Radiosensitivity 4+	
6. Tissue culture → neoplastic features	
7. Micrometabolism → neoplastic type	

Diagrammatically summarized, this indicates that lymphatic leukemia, when neoplastic in origin, begins in a localized focus of neoplastic lymphocytes, either immediately characterized in the blood by lymphemia or after an indeterminate period during which time blood examinations appear normal

With this approach, all diseases that are primary in the lymphocyte belong in one of these three categories, and if these categories are in fact separate and distinct entities, as suggested by the completion of figure 2, they should as groups present distinct characteristics of various kinds. This is found to be true, as analysis of many cases of each of the three groups shows distinctions in the clinical course, autopsy findings, condition of the cells, microscopic examination, radiosensitivity, tissue culture and micrometabolism of the lymphocytes as summarized in table 1. The factual data supporting this concept have previously been published.^{12a}

THE CLINICOHEMATOLOGIC ASPECTS OF LEUKEMIA

The preceding discussion suggests that, when studied carefully, all the primary noninfectious diseases of the lymphocyte are basically states of leukemia. When defi-

narily present difficult diagnostic problems. In contrast, lymphosarcoma without lymphemia and lymphatic leukemia without lymphemia are identified usually by recourse to diagnostic measures in addition to a simple examination of the peripheral blood.

Lymphosarcoma With and Without Lymphemia.—

The present disorder in nomenclature and the indefinite criteria used in determining a tissue diagnosis in the lymphatic diseases make it impossible to compare the experience of one clinic with that of another. For example, lymphosarcoma usually means one thing to one group (with the microscopic examination, condition of the blood, clinical course and all the rest varying accordingly) and something else to another. However, if care is exercised in disqualifying for this category all lymphoid tumors that involve primarily the reticulum cell (including Hodgkin's disease) and the pseudoleukemia of Cohnheim, our experience indicates that there are few cases of lymphosarcoma, if any, which do not eventually terminate in leukemia and which run a clinical course exceeding one year. The foregoing state-

Fig. 1 (L. H., a woman aged 43) —The hematologic history in a typical case of lymphosarcoma leukosarcoma. Note that the "sarcoma" lymphocytes were not found in the peripheral blood during three periods (May 18, 20-June 21, 24-June 30, July 1). Between these periods on two occasions the values for these cells rose to high levels. At all times, however, the sternal bone marrow was composed chiefly of the pathologic lymphocytes. Interesting also is the terminal leukopenia in which the sarcoma cells constituted practically 100 per cent of the circulatory white blood cells. Charting is on a semilogarithmic scale. A section of a lymph node is illustrated in 5 and 6, figure 5.

ments adequately explain the entirely dissimilar conclusions found in different publications; for example, in a recent paper from the Memorial Hospital for the Treatment of Cancer and Allied Diseases, New York City,¹⁸ only 6.6 per cent of the patients diagnosed (histologically) as having lymphosarcoma showed blood changes of leukemia, and of all the patients so diagnosed there was a five year survival rate of 10.6 per cent. Since of the 196 cases reviewed, 184 were said to be of the reticulum cell "lymphosarcoma" type, it would appear that an indeterminate but only small number of those reported can rigidly be classed as diseases of the lymphocyte itself. Histologically, in this clinic the term lymphosarcoma is confined to lymphoid dyscrasias in which the cell primarily involved can be identified as the lymphocyte and shows morphologic alterations

TABLE 5.—Sixty-Six Cases of Lymphosarcoma-Leukosarcoma

Distribution by sex: male 40, female 26	
Distribution by age: range from birth to 65 years (0-10) 25, (10-20) 10, (20-30) 8, (30-40) 9, (40-50) 7, (50-60) 4, (60-70) 3	
Clinical onset:	
Fatigue syndrome (including pallor and adenopathy)	32 "P. A."
Adenopathy alone	6
Hemorrhage and/or purpura	12 "purp hemorrhagica"
Gastric (chiefly nausea and vomiting).	6 } acute surgical con-
Abdominal pain	3 } dition in abdomen
Rheumatic (including bone pain)	6 "arthritis"
Upper respiratory infection	5 coryza
Dyspnea (obstruction)	2

This summarizes the distribution by age and sex of 66 consecutive patients with lymphosarcoma and leukosarcoma, together with the symptoms or signs, by groups, at the onset of the disease. In the right hand column is indicated the most common diagnosis (when wrong) made by the referring physician

nite lymphemia is present, there is little difficulty in identification of the type of lymphoid disorder. Thus, lymphosarcoma with lymphemia (leukosarcoma, "acute lymphatic leukemia") and lymphatic leukemia with lymphemia ("chronic lymphatic leukemia") do not ordi-

12a. Wiseman.¹² A summarization of these data is given in the author's reprints.

18. Sugarbaker, E. D., and Craver, L. F.: Lymphosarcoma, J. A. M. A. 15: 17 (July 13) 1940.

of the neoplastic type (previously described¹¹). These tissues are rich in lymphocytic mitoses and show no increase in fibrous tissue.

When lymphosarcoma is restricted to this category, it is my experience that all cases of lymphosarcoma are basically leukemic states, neoplastic in origin and running an acute or subacute course. In my opinion this type of leukemia corresponds to the leukemia seen in laboratory animals and, for the reasons stated earlier in this paper, is fundamentally different from "chronic lymphatic leukemia." A summarization of this concept is shown in table 4.

My experience with this disease comprises 66 cases. The distribution by age and sex with the observed types of clinical onset are condensed in table 5. Almost half of these cases initially show severe anemia, often without associated adenopathy or splenomegaly. The peripheral blood when altered is myelophthisic and/or leukemic, often resembling when not leukemic that seen in pernicious anemia. Aspiration of a sample of sternal bone marrow reveals that most of the marrow tissue is replaced with neoplastic lymphocytes and, particularly in the early phases of the disease, there is often no detectable invasion of the peripheral blood with these abnormal cell forms (fig. 1). Later when lymphemia occurs samples of the peripheral blood show that the increase in white blood cells is due solely to neoplastic lymphocytes, although normal lymphocytes may always be identified, often in the same oil immersion field of the microscope, side by side with the pathologic cells. Figure 1¹⁰ shows the hematologic course of events in 1 of these patients with a typical clinical and hematologic picture of pernicious anemia, even to a histamine-

Later, as shown, the blood stream showed invasion with pathologic lymphocytes of the neoplastic type. Attention is also directed to the severe thrombocytopenia that (characteristically) developed in this patient. As figure 1 indicates, excessive thrombocytopenia may be the chief early developing feature of this disease and accounts for the

fact that hemorrhage and/or purpura in our series was the second most common presenting onset of this type of leukemia. Most cases of this variety of leukemia exhibiting hemorrhage have been referred to us as cases of essential thrombocytopenic purpura. Usually examination of the blood but often of the bone marrow is necessary to clear up the diagnosis. The third most common onset consists of abdominal symptoms, occasionally with the

urgent decision to be made for or against immediate surgery. One of the patients in this summary table presented a classic syndrome of acute appendicitis. It is our belief that the origin of these symptoms are attributable to hemorrhage in various tissues determining the localization of symptoms within the abdomen, since all showed low values for blood platelets. Joint pain, bone pain and onsets with "upper respiratory infections" were next most common as the initial presenting clinical features in our series. Two of the latter were felt to be cases of granulocytopenia by the referring physician because of the very low value for peripheral circulating granulocytes. Dyspnea was the presenting symptom in 2 cases of this series. One of these revealed a large mediastinal mass without anemia, thrombocytopenia or neutropenia and without evidence in the peripheral blood of pathologic lymphocytes (fig. 3). In this instance aspiration of bone marrow on the patient's admission to the hospital on November 22 showed only 16 per cent of the marrow elements to be lymphosarcoma cells. This was twelve days before the abnormal types of lymphocytes were found in the peripheral blood.

Attention is also called to a feature on this chart showing that lymphemic levels of 95,000 "sarcoma" cells per cubic millimeter of blood were obtained rapidly after an abrupt rise. Whether lymphemia is induced by roentgen therapy, as has been suggested,⁴ is not

Fig. 3 (H. P., a youth aged 16).—The hematologic history in a case of lymphosarcoma which eventually terminated in leukosarcoma. The plotting is on a semilogarithmic scale. Attention is directed to the plotting of two curves for the lymphocytes; when the lymphatic tissue became infiltrated extensively with the lymphosarcoma cells, the normal lymphocytes disappeared from the peripheral blood. This is comparable to the mechanism that produced the thrombocytopenia. The course of the disease was probably too rapid for the reflection of anemia in the peripheral blood except terminally, as red blood cells have a life period of at least thirty days. Note also the parallel fall in granulocytes and normal lymphocytes at the same time that the platelets disappear.

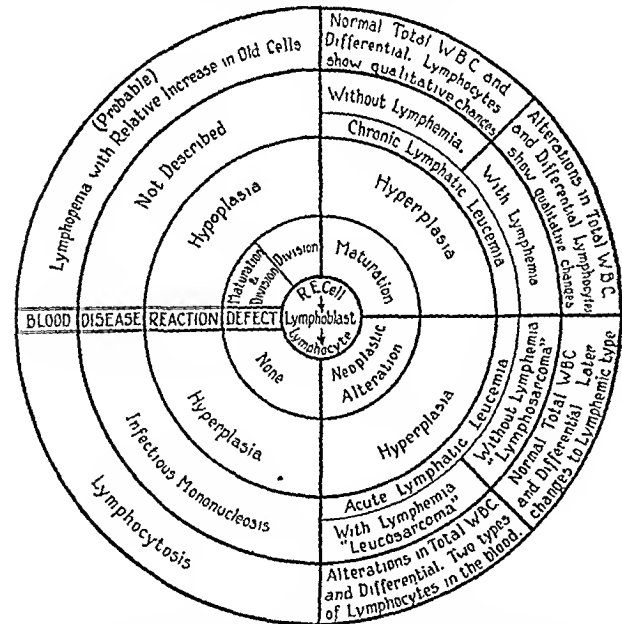

Fig. 2.—The primary diseases of the lymphocyte. Theoretically possible types of reactions of the lymphocyte with the diseases thereby produced. The second zone from the center indicates hyperplasia or hypoplasia induced by suppression of maturation and/or division occurring during the life cycle of the lymphocyte shown diagrammatically in the center. The type of disease produced by these tissue reactions is suggested in the next to the outer zone, with the type of blood reaction summarized in the outermost zone.

refractory achlorhydria. There was no adenopathy or splenomegaly. An aspirated sample of bone marrow, however, permitted identification of the disease when every other available method of examination failed.

19. All high voltage roentgen therapy of patients in this communication was given under direction of Dr. Hugh Means, roentgenologist to the University Hospital. All blood counts were made by the supravitral technic.

known. The late precipitous fall in red cells preceded by near zero platelet levels reflects the increased degree of infiltration of the bone marrow with lymphosarcoma cells, as examination at this time showed the bone marrow tissue to be almost completely replaced with this type of pathologic cell. The terminal gastric hemorrhage is attributed to the almost complete absence of platelets from the blood stream.

It is again emphasized that the diagnosis of this type of leukemia before lymphemia appears is often impossible without recourse to study of the bone marrow. When peripheral adenopathy is present, biopsy is an additional aid and reveals a variable amount of replacement of the lymph node with sheets of pale staining cells rich in mitosis, often interspersed with islands of normal lymphocytes. The diagnostic features of this variation of lymphosarcoma is summarized in table 6.

Lymphatic Leukemia.—The second mechanism that results in lymphatic leukemia bears little resemblance to that of the series of cases just cited. Other than the assumption, not supported by facts, that the leukemia of laboratory animals is identical with that occurring in man, there is little reason to believe that "chronic" lymphatic leukemia is neoplastic in origin. On the other hand, there is an appreciable amount of data that this form of leukemia is neither infectious nor neoplastic. By elimination of these two suggested etiologic theories an obscure metabolic origin would be not at all improbable. Table 7 summarizes diagrammatically my concept of a second mechanism for the production of leukemia of the benign lymphatic type.

Fig. 6 (G. Von B., a man aged 61).—Showing the fluctuations of the blood elements with high voltage roentgen treatment in case of lymphatic leukemia without lymphemia followed over a period of two and a half years. The charting is on a semilogarithmic scale. A typical sternal bone marrow differential is shown as of Nov. 11, 1940, after 1,900 r of high voltage therapy.

Lymphatic Leukemia with Lymphemia ("Chronic Lymphatic Leukemia").—Illustrative material and cases centering about this variety of lymphatic leukemia has been the subject of many papers which have been well summarized by Forkner.²⁰ When lymphemia is present

or when there is a specific alteration in the differential count a diagnostic problem is not usually encountered. Transitions between lymphatic leukemia with lymphemia and the variety without lymphemia are occasionally seen. One such case is illustrated in figure 4.

Fig. 8 (A. S., a woman aged 32, with onset at 13 years).—Showing that, exceptionally, even after twenty years of lymphatic leukemia (type Cohnheim) there may be no quantitative alterations of the cellular elements in the peripheral blood, and only moderate infiltration in the sternal bone marrow. Semilogarithmic scale.

Lymphatic Leukemia Without Lymphemia (Type Cohnheim).—This is the type of lymphoid disease that is usually diagnosed as "lymphosarcoma," "lymphocytoma," occasionally "follicular lymphoblastoma" (although this histology is unusual in lymphatic leukemia) and of course many times by the broad terms "lymphadenoma," "lymphoma" and "lymphoblastoma." With rare exceptions, the microscopic appearance of the lymphatic tissues is identical with that of lymphatic leukemia with lymphemia, but the blood shows either no distortions or only minor ones in the total number of white blood cells and/or differential. On close inspection, however, qualitative changes in the lymphocytes of the peripheral blood may usually be noted, these changes being identical with those seen in lymphatic leukemia with lymphemia. The importance of according recognition to this type of leukemia, aside from the theoretical implications, lies in the fact that not only may the clinical course and the longevity of the illness be predicted with reasonable certainty, but also more exact and adequate therapy can be given. In this type of leukemia it is especially important to understand that therapy should be directed toward the fundamental disease and not to the blood count, as illustrated by the preceding case (fig. 4). Because of the practical importance of this form of leukemia, several cases will be cited.

Figure 6 shows graphically the hematologic course in a typical case in which therapy is given. The patient was admitted to the University Hospital with the chief complaints of unsightly generalized enlargement of the lymph nodes and shortness of breath. The clinical onset occurred one year prior to hospitalization, at which time only dyspnea on exertion was noted. Four months before admission to the hospital he began experiencing dyspnea while at rest and complained of a dry, nonproductive cough. A chest plate, on admission

20. Forkner, C. E.: Leukemia and Allied Disorders, New York, Macmillan Company, 1938.

to the hospital, showed a large mass in the right middle and upper part of the mediastinum. The basal metabolic rate was plus 23 per cent. The blood count was substantially normal (fig. 6) except that qualitative alterations in the lymphocytes of a character commonly seen in lymphatic leukemia were noted. Biopsy of a lymph node showed the typical changes of lymphatic leukemia. Examination of a specimen from the sternal bone marrow showed 36 per cent of the marrow cells to be lymphocytes, all possessing the qualitative characteristics of the lymphocytes of lymphatic leukemia. The remainder of the laboratory data was not pertinent. High voltage roentgen therapy was given to the mass in the mediastinum as follows: November 30, to an anterior port 15 cm. in diameter, 150 r was directed; December 1, to an anterior port 15 cm. in diameter, 200 r; December 3, to

was 27 per cent of the marrow cells, as compared with a value of 58 per cent prior to this course of radiation therapy.

Figure 8 is particularly instructive in that it illustrates the extreme chronicity in some cases of lymphatic leu-

TABLE 6—Atypical Lymphatic Leukemia

[Mechanism: Lymphosarcoma Without Lymphemia]	
Diagnosis:	
1 Clinical:	No decisive points; extremely radiosensitive; often no adenopathy or splenomegaly; usually no fever or weight loss
2 Hematologic:	Blood picture—Always myelophthisic in type with hyperchromic macrocytic anemia and variable severity of thrombocytopenia and neutropenia Bone marrow—Aspiration shows variable replacement with neoplastic lymphocytes
3 Biopsy:	Variable degree of metastasis occurs

A summarization of the chief diagnostic facts in cases of lymphosarcoma when lymphemia is not apparent

Fig. 9 (K. T., a woman aged 40)—The hematologic history is shown on this chart in a case of lymphatic leukemia (Cohnheim) in which a high degree of infiltration by lymphocytes in the sternal bone marrow persists without depression in the peripheral blood elements. This degree of marrow infiltration usually, but as shown here not necessarily, predisposes to myelophthisic peripheral blood. The patient is also symptom free and presents only minimal adenopathy and splenomegaly. Roentgen treatment has not been necessary. The plotting is on a semilogarithmic scale.

a posterior port 15 cm. in diameter, 300 r; December 5, to a right anterior port 15 cm. in diameter, 350 r. Following this, 400 r was given to the right and left inguinal lymph nodes. Further treatment was subsequently given as shown on the chart. Following the high voltage roentgen therapy of the mediastinum, the original mass could not be visualized and all respiratory symptoms disappeared. Three weeks later the basal metabolic rate was plus 5. It is interesting to observe that no particular depression of the lymphocytes occurred in the peripheral blood, although an appreciable effect is observed on the red blood cells. Subsequent treatments with high voltage therapy show that, other than a transient anemia and mild thrombocytopenia, no adverse effects are produced in the blood, in the bone marrow or in the patient. Symptomatically, the patient each time was rehabilitated and the bone marrow reflected decreasing infiltration with lymphocytes. A typical bone marrow count is shown on the chart under date of Nov. 14, 1940, in which, after a series of radiation treatments, as indicated, the lymphocyte count in the bone marrow

kemia without lymphemia entirely comparable to the chronicity in cases of lymphatic leukemia with lymphemia previously referred to. A. S. had received high voltage roentgen therapy intermittently to control the enlargement of lymph nodes for nineteen years. The onset was at least as early as the age of 13 years, which demonstrates that this disease is not necessarily more rapid in progression in youth than in old age. The patient shows a normal peripheral blood count except for the qualitative changes in the lymphocytes that always characterize this disease. A lymph node removed at biopsy Aug. 22, 1940 revealed the typical microscopic appearance of lymphatic leukemia. An aspirated sample of sternal bone marrow reflected a mild infiltration with qualitatively altered lymphocytes (37 per cent of the marrow cells). Usually not more than 10 per cent of

TABLE 7—Second Mechanism of Production of Lymphatic Leukemia

Generalized Origin (probably not neoplastic)	
Without Lymphemia (pseudoleukemia of Cohnheim)	With Lymphemia (chronic lymphatic leukemia)
Facts in Conflict with Neoplastic Mechanism	
1 Course 3 to 25+ years	
2 Lymphocytes—morphology not neoplastic	
3 Mitosis—rare; divide by amitosis	
4 Radio-sensitivity— $\frac{1}{2}$ of lymphosarcoma	
5 Tissue culture—normal cells	
6 Micrometabolism—not neoplastic	

Diagrammatically summarized, this indicates that, when lymphatic leukemia is not the result of neoplastic changes in the lymphocyte, the fundamental alteration in the lymphoid tissues occur simultaneously throughout the body, in some instances the lymphocytes are increased in the blood, in other cases not.

the marrow cells in normal sternal bone marrow are lymphocytes, and these do not show qualitative morphologic changes. The patient continues to be in apparently perfect health and suffers the only inconvenience of occasional trips to the x-ray treatment room for reduction in size of unsightly lymph nodes.

Figure 9, which charts the course of K. T., in contrast to the preceding charts, shows advanced bone marrow infiltration with lymphocytes (89 per cent of the marrow cells), although the peripheral blood shows

no quantitative alterations, relative or absolute, of the lymphocytes contained therein. This case illustrates particularly (1) the degree of lymphocytic infiltration which may be present in the bone marrow without producing a progressive anemia, thrombocytopenia or clinical symptoms, a fact contrary to the usual experience, and (2) that, with generalized adenopathy, a lymphatic system with the characteristic changes of lymphatic leukemia (a biopsy was accomplished May 2, 1940) and a high degree of infiltration in the bone marrow, there has been no increase in numbers of lymphocytes in the peripheral blood over a period of observation of more than one year.

The diagnosis of lymphatic leukemia without lymphemia (type Colnheim) is not difficult. Clinically the important feature is the presence of long-standing adenopathy, generalized and often massive, in a patient without complaints except possibly those due to pres-

TABLE 8.—Atypical Lymphatic Leukemia

[Mechanism: Chronic Lymphatic Leukemia Without Lymphemia]	
Clinical types:	
Only one type observed; clinically often confused with Hodgkin's disease; pathologically often confused with lymphosarcoma	
Diagnosis:	
1. Clinical:	
A. Generalized adenopathy, often massive, and splenomegaly with apparently good health	
B. No fever or weight loss	
C. Urticarial or patchy erythematous rash at some time in course of disease	
2. Hematologic:	
Blood picture.—Usually normal; occasional eosinophilia; close scrutiny of lymphocytes reveals qualitative changes in these cells	
Bone marrow.—Aspiration reveals variable lymphoid content; when over 25 per cent, confirmative	
3. Biopsy:	
Usually diagnostic; identical with lymphatic leukemia; occasionally histology of "follicular lymphoblastoma"

sure by some particularly large mass of nodes in the mediastinum (cough and dyspnea) or on a nerve (pain).

My experience indicates that an erythematous, patchy, sometimes macular, sometimes papular and occasionally typically urticarial pruritic rash on the skin is especially common in this type of lymphatic leukemia. This type of cutaneous lesion occurs commonly also in lymphatic leukemia with lymphemia²² and is entirely unlike that seen in monocytic leukemia or Hodgkin's disease.²³ The chief points of aid in the recognition of this type of leukemia are listed in table 8.

CONCLUSIONS

1. A working hypothesis of the mechanisms responsible for the production of lymphatic leukemia includes two that are entirely dissimilar; one is neoplastic in origin, the other is neither neoplastic nor infectious in origin but possibly metabolic. Both types occur with and without lymphemia.

2. Disorder in nomenclature, failure to recognize the identity of the lymphocyte as a separate, distinct strain of cell and confusion of the diseases primarily involving the reticuloendothelial system with the diseases pri-

marily involving the lymphocyte have militated against and have largely prevented a rational approach to an understanding of the lymphocyte and lymphatic dyscrasias.

3. There is evidence that there are only two basic primary noninfectious diseases of the lymphocyte. Both are potentially and always in some phase of the disease accompanied by quantitative and/or qualitative changes in the lymphocytes in the peripheral blood, although the mechanism of production of each is different.

4. This concept of the primary diseases of the lymphocyte, entirely aside from the supporting scientific evidence described, works in clinical practice, permitting accurate diagnosis, acceptable prognosis and maximum efficiency of treatment.

5. Finally, it is suggested, as the result of ten years of research and experience in this field, that correct diagnosis of the lymphatic dyscrasias can be achieved in a maximum number of cases only by the clinician-hematologist, who must consider, in the aggregate, the clinical features, peripheral blood, bone marrow and microscopic condition of the lymphatic tissue before a decision as to diagnosis can be given. The pathologist's interpretation of the lymph node alone often does not suffice. This is applying to the lymph node diseases a principle that has been established as valid through experience in the remainder of the blood dyscrasias.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. BETHELL AND WISEMAN

DR. RUSSELL L. HADEN, Cleveland: No disease puzzles me more or presents a more bizarre clinical picture than leukemia. It is a complex problem. The patient with unexplained fever and unexplained anemia must always have leukemia considered as a possible cause of his disease. Even after the diagnosis of leukemia has been correctly made, it often is impossible to be sure about the type. Dr. Bethell, after further study, has had to revise the original diagnosis in 10 per cent of the cases. The frequency of leukemia without leukocytosis should be emphasized. Dr. Bethell calls this the subleukemic form and Dr. Wiseman the atypical form of leukemia. Dr. Bethell told me this morning that 20 per cent of his series of patients are subleukemic. About 25 per cent of our patients with leukemia of all types never show a leukocytosis. The leukemia may be just as malignant with 2,000 as with 200,000 cells. My associates and I have been helped greatly in making the diagnosis of leukemia in the absence of leukocytosis by a careful study of concentrated preparations of the white cells. Dr. Bethell has emphasized the great variety of symptoms encountered in leukemia. The patient may have almost any symptoms since the disease is so widespread, although fever and anemia are by far the most common. Only 10 per cent of Dr. Bethell's group of patients with acute lymphoblastic leukemia had any enlargement of the spleen and lymph glands. The outlook for treatment in acute lymphoblastic and the lymphosarcoma cell types of leukemia is very poor. Perhaps the patients are much better off if nothing is attempted. I am impressed with the important place of arsenic in the treatment of chronic leukemia. I prefer to use it in combination with iodine. Many patients with chronic lymphatic leukemia judiciously treated with irradiation and arsenic will get along exceedingly satisfactorily often for years.

DR. SHIELDS WARREN, Boston: In the discussion of leukemia this morning, one thing has stood out more than anything else: our relative ignorance of the disease in spite of all the attention that has been focused on it. As brought out by Drs. Bethell and Wiseman, I believe this ignorance has been due partly to a one-sided type of study. I am glad to hear them emphasize the need for consideration not only of the blood findings but of the clinical findings, also taking into consideration the micro-

scopic appearance of the lymph nodes and in the bone marrow as shown by biopsy. As a pathologist who has studied cases of chronic lymphatic leukemia at autopsy I cannot entirely agree with Dr. Wiseman in considering it as not a neoplastic disease. The extent of infiltration of the various viscera in the cases which do come to autopsy make me feel that until we have strong evidence to the contrary it is best retained in the neoplastic group.

DR. RAPHAEL ISAACS, Chicago: I was aware of the fact that the subject of leukemia is complicated, but I see it is even more complicated than I thought. The present concept of lymphatic leukemia may be simplified if we consider that there are really three conditions. One is a hyperplasia, or overgrowth of cells of the lymph glands. The second is an overgrowth of cells of the spleen. The third is a neoplastic condition which we may call lymphosarcoma. The cells of the lymph glands have round nuclei. The cells of the spleen have oval or kidney shaped nuclei. In other words, the spleen is not a lymph gland. So we have two kinds of lymphatic leukemias so called, one in which there is an overgrowth of lymphocytes and one in which there is an overgrowth of cells in the spleen. There may be lymphocytes invading the spleen or there may be spleen cells invading the lymph glands, but they are two different diseases, and I think the outlook in the two is quite different. At present I agree with Dr. Wiseman that there is a possibility that the lymphatic leukemia is hyperplasia of lymphoid tissue and that lymphosarcoma is a neoplastic condition. Some conditions appear to be converted into the neoplastic type by roentgen treatment. In fact, most of the patients with lymphosarcoma who became leukemic received roentgen treatment before they became leukemic. A therapy which we found helpful was that if the patients eat about half a pound of liver every day their red blood cell count and hemoglobin content remain nearer normal for a longer period of time than otherwise. Liver extract will not have this effect, but there is something in whole liver which influences the red blood cell count and hemoglobin in chronic lymphatic leukemia.

DR. B. K. WISEMAN, Columbus, Ohio: I don't think it possible at present to convince every one that there are two fundamental types of leukemia, one neoplastic and one non-neoplastic. As in the case of pernicious anemia, this will probably require the added evidence of therapeutic control. When I first started in this field, I also thought that all types of leukemia were neoplastic and I think I was unduly swayed in my judgment because of the animal types of leukemia—laboratory leukemia. After careful study of this disease, taking into consideration the clinical course, the morphologic aspects of the cells involved, the type of pathologic change that occurs in the lymph nodes with certain laboratory indications, such as the micro-metabolism and tissue culture characteristics of these cells, it became evident to me that the so-called chronic type of lymphatic leukemia did not seem to possess many of the recognized traits of neoplasms in general. I think the leukemia of the laboratory animals is represented in the human field by the acute lymphatic type which does show neoplastic traits. This is also termed "lymphosarcoma cell leukemia" or "leukosarcoma." I think this concept makes quite clear any lack of conflict between the established facts of animal leukemia and those of human leukemia. I don't think "chronic" lymphatic leukemia is ever found in laboratory animals. Dr. Warren, of course, has all the data I presented in my written paper in support of the non-neoplastic hypothesis of chronic lymphatic leukemia. Time does not permit a satisfactory rebuttal based on factual evidence, but I listed these facts on the lantern slides although I didn't have time to emphasize them. Necessarily, I must be content to rest my case on the basis of the merits of the material developed in the written manuscript. With reference to Dr. Isaacs' remarks, I would say that I have not seen a chronic type of lymphatic leukemia which terminated in the lymphosarcoma type of leukemia. Assuming no inaccuracies in identification of cell types I would interpret this phenomenon as a coincidental occurrence of two separate disease states in the same individual. This would necessarily be an extremely rare occurrence.

CLINICAL VALUE OF THE ASCHHEIM-ZONDEK TEST IN THE DIAGNOSIS OF TESTICULAR TUMORS

GRAY H. TWOMBLY, M.D.

HAROLD M. TEMPLE, M.D.

AND

ARCHIE L. DEAN, M.D.

NEW YORK

Since 1931 quantitative Aschheim-Zondek tests have been done routinely on patients with testicular tumors at Memorial Hospital. There have been 203 such patients, on whom a total of 1,403 urinary assays have been recorded. The tests were performed by the technic described by Ferguson in 1933. In addition there have been 42 on whom tests have been done with a larger number of animals per test in an attempt to make the assays more accurate. We wish to analyze data on these patients to answer the following questions:

1. Is the amount of hormone in the urine of a patient with a testicular tumor related to the histologic structure of the tumor?
2. Can one accurately follow the clinical course of the disease by repeated Aschheim-Zondek tests? Do these tests show increasing excretion of hormone, for instance, as evidence of recurrence or metastasis before such conditions can be discovered clinically?
3. Is the Aschheim-Zondek test as originally performed by us accurate, and if not why not?
4. Has the test any prognostic value in cases of testicular tumors?
5. Finally, is the test of sufficient clinical value to be worth doing? If it is, how should it be done?

Historically, the appearance of gonadotropic hormone in the urine of a man with teratoma testis was first observed by Zondek in 1929¹ and reported, with a subsequent case, in March 1930. In September 1930 Heidrich, Fels and Mathias² published a detailed study of a case of chorioepithelioma of the testis, with data on the hormone in the urine. Ferguson's³ first paper, based on a study of 12 cases, appeared in April 1931. The observation was made that irradiation caused a fall in the hormone output. In June 1933 Ferguson published a more extensive article,⁴ reporting on a series of 117 consecutive testicular tumors studied by quantitative tests for gonadotropic hormone. From this material he came to the conclusion, reiterated several times in other articles,⁵ that the histologic type of the tumor could be predicted by the amount of hormone excreted in the urine. For choriocarcinoma, 40,000 or more mouse units of prolan A per liter was given as characteristic; for embryonal adenocarcinoma, 10,000 to 40,000 mouse

units; for embryonal carcinoma with lymphoid stroma, 2,000 to 10,000 units; for seminoma, 400 to 2,000 units, and for adult teratoma, 50 to 500 units.^{5a} The statement that "the limits reached by each type of tumor overlap so little that it is possible to make the diagnosis on the basis of this determination alone" is found in an article published by Ferguson in March 1934.⁶

We have examined data in our files on 203 patients on whom satisfactory quantitative Aschheim-Zondek tests have been done to determine whether the foregoing statement is correct. For this purpose we limited ourselves to patients who had either an untreated primary tumor at the time of the first test or active untreated metastatic disease. Only 14 had tests of the urine done when a primary untreated testicular tumor was present and subsequently showed classifiable tumor tissue either on orchiectomy or biopsy of a metastasis or at autopsy. Thirty-six had urinary assays after the primary testicular tumor had been treated by irradiation or orchiectomy, with active untreated metastatic disease present when the assays were made.

For these reasons, therefore, only 50 patients of the 203 provided a suitable basis for answering the first question, regarding the correlation between the amount of hormone in the urine and the histologic structure of the tumor. The remaining patients fell into various classifications. For instance, some never showed any positive evidence of active disease while in this hospital, having come here for prophylactic irradiation. Others had been treated successfully here many years before the test was used and have remained clinically cured. Still others were given radiation therapy before a sample of urine was collected. Some refused orchiectomy, and no pathologic specimen was obtained. Some showed such complete destruction of the tumor by irradiation that no pathologic classification could be made.

Of the 50 tumors found suitable, 2 were adult teratoma, 3 were adult teratoma with areas of embryonal carcinoma, 4 were embryonal carcinoma, 20 were embryonal carcinoma with lymphoid stroma, 14 were embryonal adenocarcinoma and 7 were partially or completely choriocarcinoma. The last 7 may be further divided into 2 which were choriocarcinoma throughout, 2 which were embryonal adenocarcinoma with areas of choriocarcinoma and 3 which had areas said to be suggestive of choriocarcinoma. This classification appears in figure 1, in which it is also shown that the 2 patients in whom the tumor had strictly adult features excreted 0 to 500 mouse units per liter of urine. This was true also of 1 of the 3 patients in whom the tumor was adult and contained areas of embryonal carcinoma. The other 2 excreted 1,000 to 2,000 units per liter.

In the 4 cases of embryonal carcinoma there was no uniformity of hormone excretion, the amount ranging from 0 to 10,000 mouse units. The same lack of uniformity in hormone output was shown in the 20 cases of embryonal carcinoma with lymphoid stroma and in the 14 cases of embryonal adenocarcinoma. In general the more widespread the tumor the higher the hormone output; but this principle is not of much clinical use, because of frequent exceptions. For instance, there

were 2 cases of embryonal carcinoma with lymphoid stroma and 3 of embryonal adenocarcinoma with extensive untreated metastatic disease in which only 100 to 500 mouse units was excreted per liter of urine.

In the 7 cases of either frank choriocarcinoma or areas suggesting it the excretion rate was high.

In the 50 suitable cases we made no attempt to reevaluate the laboratory tests but merely used the figures as they had been placed on the charts. From the foregoing discussion it can be seen that there is no close relation in this material between histologic type and rate of hormone excretion. In general, however, when

Fig. 1.—Data on 50 cases of teratoma testis in which quantitative Aschheim-Zondek tests were done on the urine when active untreated disease was present. The amount of hormone excreted and the clinical extent of the disease are shown.

the tumor is of one of the less malignant adult types the excretion level tends to be low, while the choriocarcinoma causes the highest levels.

As mentioned previously, 42 cases have been studied in a more intensive fashion, with more mice per level than were used in the earlier tests. Of these 42, 19 are suitable for analysis. The remaining 23 are made up of 8 in which there were nonmalignant testicular swellings, 2 in which pathologic examination was not done, 8 in which there was no evidence of active disease at the time of the first test or subsequently and 5 in which the pathologic reports were unsatisfactory (because of destruction of the tumor or some other reason).

Among the 19 patients were 2 with choriocarcinoma. One of these excreted 200,000 mouse units per liter of

5a. By prolan A is meant a gonadotropin hormone which causes follicle ripening. No distinction was made between hormones of pituitary and those of placental origin.

6. Ferguson, R. S.: Clinical Evaluation of the Quantitative Excretion of Prolan A in Teratoma Testis, J. Urol. 31: 397-409, 1934.

urine, and the other only 100 to 150. Among 11 with embryonal adenocarcinoma 1 excreted 64,000 mouse units per liter; 1, 40,000; 1, 5,000; 4, 2,000; 1, 400, and 3, 100 or less. All these patients had extensive metastases except the man excreting 40,000 units and the 1 excreting 400 units per liter. The first patient had a tumor in a testicle only. The second had a few metastases.

Among 5 patients with embryonal carcinoma with lymphoid stroma or seminoma there was 1 who excreted 20,000 units, 1 who excreted 1,000 and 3 who excreted less than 200 units. All 5 had fairly extensive metastases.

One patient with myosarcoma with metastasis excreted 400 units per liter.

In answer to question 1, then, our experience is that there is no definite correlation between hormone level and histologic appearance of the tumor. One cannot make the diagnosis seminoma, embryonal adenocarcinoma or even choriocarcinoma from data on the hormone excretion alone.

This is hardly surprising when one considers the histologic complexity of many of these tumors. Tumors classified as embryonal adenocarcinoma may show areas of complex teratoma, with various types of tissue, derived from other germ layers, present. Ferguson⁷ himself, after study of 80 testicular tumors by large serial sections through the entire tumor, concluded:

The malignant tumors of the testis are the result of neoplastic growth of the germ cell, and because this cell under certain circumstances (age, location, hormonal condition of the host) may exhibit but one or all of its potencies, these tumors are in a strict sense, teratoid in origin.

He mentioned a specimen in which chorioepithelioma, embryonal adenocarcinoma and seminoma were found in adjacent areas.

The tumor of the patient with embryonal carcinoma with lymphoid stroma in our last series who excreted 20,000 units per liter was typical in the first slide examined but in another area showed epithelial-lined cysts. Since most of the diagnoses used in answering our first question were made from small blocks of tumor, it is easily understandable that more complete examination of the entire tumor or of the metastases, were this possible, might give a different impression.

Can one follow the clinical course of the disease by repeated Aschheim-Zondek tests and predict metastases before they are clinically evident?

In answering this question we have relied chiefly on the 203 cases originally studied. Of the 203, 48 were not suitable, either because not enough information as to the clinical course was available or because only one assay was done.

In 74 cases no test yielded a level above 500 mouse units per liter; these cases are not considered, because consistently low levels cannot be used to affirm or deny the supposition that the excretion level follows the clinical course of the disease.⁸

In 47 cases there seemed to be close correlation between hormone levels and clinical course. In many of these there were consistently high levels of hormone which corresponded with clinical progress to a fatal outcome. In others a fall of hormone output appeared with intensive treatment and a rise with the appearance of metastasis.

In 34 cases, on the other hand, either rising hormone levels were not associated with progress of the disease or falling levels accompanied progressive cancer. Possibly the former occurrence may be explained by an increase in the excretion of pituitary gonadotropic hormone known to follow castration.

Obviously, a test which in only 47 of 155 serial determinations shows close correspondence with the condition of the patient is of little clinical value. Is it possible to find any reasons for this failure of correlation? It would seem reasonable to suppose that when a tumor produces a measurable amount of hormone increased growth will be accompanied by increased hormone output, and vice versa. That this was true in some of the 47 cases suggests that the exceptions must have an easy explanation.

In the technic devised and advocated by Ferguson and used in this laboratory until three years ago, 6 mice were used for each test. Five injections of a different amount of fresh morning urine or varying quantities of a 5X alcoholic concentrate of this urine were given each mouse in two days. That is, only 1 mouse was used to determine the response at each of six different levels. When the animals were killed one hundred hours after the first injection, the final values were obtained by considering the formation of follicles in the ovaries as constituting a positive reaction. Thus if the mouse which received five injections of 0.2 cc. (1 cc.) of fresh urine showed follicle formation, it would be recorded that 1 mouse unit of hormone was present in 1 cc. of urine, or 1,000 units in a liter. If corpora lutea appeared, Ferguson multiplied by five the values obtained by the foregoing method, since Zondek had shown that it took approximately five times the amount of the urine of pregnancy to cause the formation of corpora lutea that it did to produce the ripening of follicles.

This method contains at least four sources of error:

1. Laboratory animals are so variable in their reactions to biologic products that to rely on only 1 animal per level is hazardous. This is shown by a study of the 42 cases in which 5 mice were used for each similar quantity of urine injected. In these cases, 430 tests were made on 2,150 mice. Of the 430 tests, 118 revealed the formation of corpora lutea or corpora haemorrhagica in the ovaries of at least 1 of the 5 mice. In other words, gonadotropic hormone appeared to be present. Yet in only 43 of these 118 tests were positive results obtained on all 5 mice. In 26 tests 4 of 5 mice showed corpora lutea; in 14, 3 of 5; in 18, 2 of 5, and in 17, 1 of 5; yet it is obvious that hormone must have been present to cause the formation of corpora lutea in even the last group.

2. To use a first morning specimen and calculate amounts of hormone per liter introduces variable factors such as the efficiency of the patient's kidneys and bladder and the amount of fluid he consumed the previous evening. A man with a daily output of 3,000 cc. of urine will not show the same amount of hormone per liter as one putting out exactly the same total quantity in 1,000 cc. A patient whom we studied carefully with serial daily hormone determinations suddenly increased his output of urine from 1 liter to 5 while under observation, explaining when questioned that he thought it was "a good thing to drink plenty of water." Only twenty-four hour collections are rational in such a metabolic study and, as a matter of fact, well preserved three day collections would probably give even more accurate results.

7. Ferguson, R. S.: Teratoma Testis: Pathogenesis of the Malignant Tumors of the Testis, Preliminary Note, Cancer Probl., Symposium, 1937, pp. 86-91.

8. Variations from 100 to 500 units probably are meaningless with the technic that was used.

3. To make a 5 \times concentration of urine by precipitation with 95 per cent ethyl alcohol is to invite error. Alcoholic precipitation appears to be among the most satisfactory procedures for concentrating and recovering gonadotropic hormone, but the amount so recovered is highly variable. We have had the experience of finding no hormone in an alcoholic extract of a specimen of urine which showed appreciable amounts when unconcentrated. By the statement that this process invites error we do not mean to deny the value of concentrating urine by alcoholic precipitation but wish to point out the fallacy of supposing that such a procedure gives 100 per cent recovery of hormone.

4. To take as an end point the formation of follicles in the ovary and to assume that five times the amount of hormone which causes this result will produce corpora lutea is wrong. At least two gonadotropic hormones now are known to occur in urine. These are the follicle-stimulating hormone from the pituitary, found in

one or two of the many follicles present show development. It is necessary, then, to record values in levels of chorionic gonadotropic hormone and follicle-stimulating hormone separately and to control one's observations by microscopic section of the ovaries of the experimental animals.

If we have shown that the quantitative Aschheim-Zondek test as it can be carried out practically has little value in disclosing the type of the testicular tumor or in accurately following the clinical course of the disease, is it of any clinical value? We believe that this question should be answered in the affirmative, because our records show that the appearance of chorionic gonadotropic hormone is a bad prognostic sign. Of the original 203 patients with testicular tumor studied, those who showed a hormone level which never went above 1,000 mouse units per liter had a mortality of 33 per cent. This means that, of all patients tested from 1931 to 1939, 77 per cent were alive in July 1939.

Fig. 2.—*A*, ovary of a mouse inoculated with urine from a patient showing no gonadotropic hormone. *B*, ovary of a mouse inoculated with urine from a castrate. Note that nearly all follicles show ripening but no corpora lutea are present. This effect is due to the presence of follicle-stimulating hormones, probably from the anterior lobe of the pituitary gland. *C*, ovary of a mouse inoculated with urine from a patient with active teratoma testis. Note that there is only one ripe follicle at the top of the section but a corpus luteum at the bottom. This effect is due to the presence of chorionic gonadotropic hormone.

large amounts in the urine of male and female castrates and of women past the menopause, and the chorionic gonadotropic hormone of the urine of pregnancy (fig. 2). The latter causes luteinization of follicles already formed, and in the hypophysectomized rat the effect is one of luteinization of interstitial cells. The action of the follicle-stimulating hormone is primarily the formation of follicles. Both hormones are found in the urine of patients with teratoma; occasionally they may be present together, but it is likely that one may predominate over the other. A patient studied by us repeatedly had positive reactions at 1,000 to 2,000 mouse units per liter though clinically free of disease. Microscopic study of the assay mouse ovaries showed ripening of all visible follicles, with either no corpus luteum or only an occasional one. The positive reaction was a castration effect. On the other hand, specimens of urine may give rise to many corpora lutea and few ripe follicles. Diluting such urine does not result in the picture of profuse maturation of follicles described but rather produces a condition of the ovary in which only

If a patient excreted 1,000 to 2,000 mouse units of hormone per liter he belonged to a group of which 57 per cent were dead on that date. Those excreting 2,500 mouse units or more per liter showed an 82 per cent mortality.

Thirty patients were recorded as excreting 10,000 mouse units or more per liter. All who showed this amount on more than one occasion are dead.

Of the 42 patients studied more carefully for level of excretion and type of hormone, the urine of 18 in some dilution gave rise to corpora lutea of the pregnancy type in the ovaries of the test animals. Of the 18, 14 died in less than three years, while 1 is still living but has extensive metastatic disease. The 3 patients apparently cured are 1 whose highest output was 200 mouse units per day of what appeared to be chorionic gonadotropic hormone, a second whose urine showed in a single test 10,000 mouse units of this type of hormone until removal of the tumor, after which it showed only small amounts of follicle-stimulating hormone, and a third with metastatic seminoma, whose urine never

produced corpora lutea but did produce follicle ripening, suggesting the presence of chorionic gonadotropic hormone, excreted in amounts of 100 units every twenty-four hours.

Of 16 patients whose urine showed small amounts of what appeared to be follicle-stimulating hormone or no hormone at all, 13 are living and apparently free of disease, while 3 have died. We have been unable to confirm the suggestion of Hamburger⁹ that follicle-stimulating hormone is found in the urine of patients with seminoma (for him a term including embryonal carcinoma and embryonal carcinoma with lymphoid stroma) and chorionic gonadotropic hormone in that of patients with adenocarcinoma or chorioma. Both types of hormone are found in each group of patients, we believe.

Finally, from the clinical point of view is the Aschheim-Zondek test worth doing in all cases, and if so how should it be done? We believe that the test is valuable, since positive results are of grave prognostic value and not infrequently constitute the only evidence of disease. An example of this is a recent case in which the diagnosis originally was tuberculous epididymitis on the left. Two tests were done on the urine before any treatment was begun, and each revealed a considerable quantity of chorionic gonadotropic hormone. On the basis of these tests a diagnosis of teratoma testis was made, and it proved to be correct on orchiectomy. After operation and roentgen therapy the test continued to give positive results, though there was no clinical or roentgenologic evidence of disease. Eleven months after operation, there being increasing excretion of hormone in the urine, metastatic disease in the mediastinum was finally found by roentgenogram.

We believe that the test can be satisfactorily performed in the following manner: A twenty-four hour collection of urine should be assayed on 6 mice as recommended by Ferguson. If any react positively, quantitative determinations should be performed. At least 5 mice should be used for each assay level and the ovaries of all animals should be studied histologically. Uniform ripening of follicles, suggesting the pituitary type of hormone (follicle-stimulating hormone) seems to be of little prognostic significance. The formation of corpora lutea, especially of the chorionic hormone type, is important. A negative reaction is of little clinical significance because considerable disease may be present. A strongly positive reaction of the chorionic type is highly important because, according to our experience, it signifies active disease and usually a fatal prognosis.

SUMMARY

1. A study of 203 cases of testicular tumor in which quantitative Aschheim-Zondek tests were done by the method of Ferguson and a study of 42 cases in greater detail, with a larger number of mice per assay level, revealed little correlation between the amount of gonadotropic hormone found in the urine and the histologic type of the tumor.

2. In only 47 of 155 cases in the series followed by serial tests done by Ferguson's technic was there any close correlation between the hormone level and the clinical course of the disease.

3. The failures in correlation may be ascribed to the inadequacy of the test as originally described.

4. The presence of chorionic gonadotropic hormone in the urine means that there is an active tumor somewhere in the patient and suggests a bad prognosis. Eighty-two per cent of the patients whose urine showed 2,500 or more mouse units per liter are dead. All patients who excreted 10,000 mouse units per liter more than once are dead. In the test as used, "10,000 mouse units" indicates the presence of chorionic gonadotropic hormone.

5. By suggestions given for doing the quantitative Aschheim-Zondek test, a number of errors in the former technic may be corrected.

York Avenue at Sixty-Eighth Street.

ABSTRACT OF DISCUSSION

DR. JOSEPH H. KIEFER, Chicago: We do not see nearly so large a number of cases in Dr. McKenna's service at the Research and Educational Hospitals of the University of Illinois, but in the last four years we have determined the gonadotropic hormone output in every one. The Zondek alcohol precipitation method has been used routinely. This gives a set of values which differs considerably from that obtained when unaltered urine is used. In some cases, in which we made parallel determinations with both extract and unaltered urine, a ratio of approximately 3 to 1 was found to exist. Some of the earlier reports proposed that one could determine the type of tumor present by the titer of the hormone output. Also it was said that one could determine the presence of metastases with assurance and regulate roentgen therapy accordingly. Some authors even proposed a classification of these tumors in which the primary standard of division would be hormone output, and the secondary divisions into subgroups would be made according to the histologic picture. A few reports have appeared since in which the value of this method has been denied. We have found that routine use of this test has been useful in diagnosis. We have found no positives in nonmalignant lesions. Several of these cases were so suggestive as to warrant surgery despite the negative hormone output. In every case the lesion has proved to be nonmalignant. We have so far had no case of tumor in which a preoperative determination was negative. We have not been able to correlate the histologic type and hormone output in any more than a very inexact way. Likewise extent of metastasis did not give a corresponding increase in hormone output. Some patients with extensive demonstrable metastases showed only minimal hormone outputs. Some others, apparently well after orchiectomy and roentgen therapy, continued to show these same low values for years (possibly a castration effect). Hormone determination is a valuable aid to diagnosis and, with definite restrictions, in prognosis. Possibly with further knowledge as to the exact nature of the hormone formed, tests of this nature will take on added value. In many cases gonadotropic hormone may be only one of several hormones elaborated by these growths. If these totipotent cells can elaborate gonadotropic hormone, why not estrogens and others? How else can one explain gynecomastia with colostrum formation? Some investigators have found estrogen excretion in these cases.

DR. J. B. GILBERT, Schenectady, N. Y.: It is important to remember that frequently the original technic is the best, and modifications often increase the difficulties of its proper application. This test must be done in great detail, which allows no short cuts. This detailed and expensive work is often possible only in research institutions. From the practical standpoint in the vast majority of patients as seen by urologists in smaller hospitals the procuring of exact quantitative tests is frequently impracticable or often actually impossible. The test as used in most hospitals is poorly standardized, as some use mice, others rats, and many rely on a single intravenous rabbit injection. A summary of the results and the true importance of such tests is almost impossible to determine by reference to the collected urologic literature. The correlation between hormone levels and pathologic type is extremely difficult because of possible errors in both the microscopic examination of tissue and the aforementioned errors in endocrine methods. Confusion in this

9. Hamburger, C.; Bang, F., and Nielsen, J.: Studies on Gonadotropic Hormones in Cases of Testicular Tumors: Attempt at Classification of Testicular Tumors on the Basis of Their Hormonal, Histological, and Clinic-Radiological Properties, *Acta path. et microbiol. Scandinav.* 13: 75-102, 1936.

subject has been caused by misdefinition and inexact terminology. This confusion arose in Aschheim-Zondek's original description of reactions I, II and III and was later increased by the use of the terms "prolan A and B." The fact that the origin of the so-called prolans is not known for certainty makes an exact definition difficult, if not impossible. The authors' use of the term "chorionic gonadotropic hormone" is useful and should be followed by others. The fact that the finding of such a hormone, with corpus luteum formation in the ovaries, indicates a bad prognosis is extremely important. This was found to hold true in our study of personal and collected cases in which testis tumors were associated with gynecomastia, also in another series of small obscure primary testis tumors in which hormone assays aided in the early diagnosis and prognosis in 21 of 53 cases. The clinical course when based on histologic grading has been inexact, and only to a moderate degree have the hormonal tests clarified this situation. The authors do point out, however, that a roughly useful working guide to prognosis and therapy can be obtained; also that at least positive findings are important and may constitute the only evidence of disease. Together with the aid of these tests and the expert knowledge gained from treatment of many patients, the survival rate in their hands at the Memorial Hospital is unusually large. A 14 per cent survival in inoperable testis cancer treated under these conditions is proof of their careful and intelligent clinical management and valuable aid received from the laboratory.

Dr. GRAYSON CARROLL, St. Louis: The authors speak of orchietomy. Do they attempt to remove the retroperitoneal lymph glands in their operative procedure or have they abandoned that? I am aware that in most of the textbooks it indicates that that should be done whenever possible.

Dr. GRAY H. TWOMBLY, New York: Dr. Kiefer's report differs from ours in that he seemed to find positive hormone tests in all his cases. I could mention a dozen cases in our clinic in which there was a testicular tumor present, but no hormone. I wonder whether he made any study of what type of hormone was present. It is possible the tumor itself growing in the testis and destroying it may influence the pituitary to secrete the castrate type of hormone. Our experience is that only a positive test is of diagnostic value and a negative test means nothing. I have seen a case in which the lungs were filled with metastases that had an absolutely negative test as far as we could determine. He said something about estrogens in these cases. We ran estrogenic determinations on one man who had a chorioepithelioma of the testis with gynecomastia. He had a titer which was about twice as high as that of the normal female and, of course, a great deal higher than that of the normal man. But I don't believe that much estrogen is excreted in most cases of teratoma testis. Dr. Gilbert was complimentary about our handling of these tumors. I didn't quite like his saying he felt that the test was not practical. I feel that the study we have made really makes the test more practical than it was before, because it appears that repeated tests to try to follow the course of the disease are not worth while doing in most cases but that the test in which we try to find out whether the patient is excreting chorionic gonadotropic hormone or not is tremendously worth while. All the people that really excreted it in large amounts died of the disease. He brought out the variability in microscopic appearance of teratoma. There can be a choriomatous tissue in one part of the tumor, seminoma in another part, adult type of tumor in another part, embryonal adenocarcinoma in another part. In answer to Dr. Carroll's question it has been the policy at Memorial Hospital to do the orchietomy only after the roentgen therapy. However, it seems to me that, if one exposes the cord and ligates it carefully, one cuts off all the lymphatics. There isn't any possibility of spread taking place up the cord while one is manipulating the testis, if one has already cut the lymphatic channels. Then the tumor can be lifted out of the scrotum, giving a gross specimen that one can really study properly in the laboratory, both pathologically and from the hormone point of view. It has been the feeling of the men in the urologic department that wide dissection of the nodes in the iliac region, as Dr. Hinman does, is a procedure that does not give a high enough cure rate to justify the risk to the patient in that procedure. The routine treatment has been to treat the testis and then the iliac and epigastric regions with large amounts of roentgen ray.

THE TECHNIC OF BRONCHOGRAPHY AND A SYSTEM OF BRONCHIAL NOMENCLATURE

RALPH ADAMS, M.D.

AND

LOWREY F. DAVENPORT, M.D.

BOSTON

As refinements in the technic of pulmonary resection have lowered mortality and morbidity rates, the medical profession and the group of patients symptomatically concerned have become increasingly interested in the possibility of relief from cough or sputum and the number of cases requiring critical evaluation has risen sharply.

Bronchography, as roentgen demonstration of the bronchial pattern by opaque mediums is called, is an essential diagnostic aid in the investigation of many such patients, and the use of the procedure has become widespread during recent years. Commendable as is the enthusiastic study of patients with a cough by all measures likely to discover its cause, the general use of iodized oil injection has raised certain problems. Numerous patients have been seen in consultation in whom a diagnosis of bronchiectasis has been established elsewhere by demonstrating iodized oil filling one or more grossly dilated bronchi in one or more lower lobes. The filling is adequate for substantiating a diagnosis of bronchiectasis but inadequate for a basis on which to plan a surgical program, and the patient must be requested to undergo another injection. Oftentimes objections are encountered because the initial procedure is recalled as a nightmare, attended by violent coughing, nausea, vomiting, excitement and general confusion. Patients sometimes also are inquisitive as to why the original injection was not done in such a manner as to give the information required.

We have done several hundred iodized oil injections in the past seven years by various methods¹ and have developed a simple, proved technic which is almost uniformly successful and is suitable for use by any physician willing to learn a few principles and respect scrupulously the details of application. The time has come when an accurate, complete, intelligently made bronchogram can reasonably be expected of any one who undertakes the procedure. No longer is it sufficient to succeed in getting a few drops of iodized oil into some part of the tracheobronchial tree; on the contrary, every bronchial segment should be visualized in order that the extent of the disease may be established and a proper plan of therapy instituted. Especially is this important if surgery is indicated, because decision concerning the amount of lung tissue to be resected must rest largely on the bronchogram.

TECHNIC

The technic requires simple materials, and no special equipment is needed. Adequate facilities for making good x-ray films of the chest are assumed. The materials required are:

(a) Two chairs, a small work table, an adjustable electric light and a flat-top table.

From the Thoracic Clinic of the Massachusetts General Hospital.
Read before the Section on Laryngology, Otology and Rhinology at the Ninety-Second Annual Session of the American Medical Association, Cleveland, June 6, 1941.

1. Goldman, Alfred, and Adams, Ralph: Endobronchial Probing Combined with Serial Selective Bronchography Fluoroscopically Controlled, *Ann. Surg.* 106: 976 (Dec.) 1937.

(b) A head mirror, a laryngeal mirror, an atomizer, 6 inch cross forceps, small cotton or gauze pledgets, a 2 cc syringe and curved applicator, an ordinary number 16 urethral catheter and stylet and a 20 cc syringe (fig. 1).

(c) A 5 cc. measuring flask, two 5 cc. glass containers, 4 per cent cocaine, 5 per cent larocaine and 20 cc. of iodized oil.

PRELIMINARIES AND ANESTHESIA

Preoperative medication is not essential but is beneficial in achieving abolition of cough, a suppression of mucous membrane secretions and proper introduction of oil. A small dose of pentobarbital one hour beforehand helps allay nervousness and acts as a specific prophylactic antidote to cocaine hypersensitivity. In our hands the preliminary medication with pentobarbital has prevented severe cocaine reactions. These most often occur in apprehensive persons of the sympatheticotonic type. The initial reaction is largely due to the vasomotor effect and can be promptly relieved by the inhalation of amyl nitrite. A dose of morphine

A sitting position should be used for the induction of local anesthesia to the throat and tracheobronchial tree. The physician should sit opposite with the small work table and materials at his right and a light behind the patient's shoulder. Good anesthesia is prerequisite to good bronchography. This statement cannot be over-emphasized, and it can be stated with almost equal truth that poor bronchography is due mainly to poor anesthesia. A large quantity of anesthetic is not desirable and, in fact, is contraindicated. Proper topical application of 10 cc. of 4 per cent cocaine hydrochloride solution or 5 cc. of 4 per cent cocaine and 5 cc. of larocaine gives an excellent preparation with abolition of the involuntary cough reflex. Our custom is to spray the pharynx with 3 cc. of 4 per cent cocaine, swab each piriform sinus and the epiglottis with 1 cc., and inject 5 cc. of 5 per cent larocaine down the trachea. Larocaine is used for intratracheal instillation because of its theoretical advantage of lowered toxicity in comparison with cocaine. No reaction has been encountered with either agent.

INSERTION OF CATHETER

The method used is similar to that described by Baker.² The urethral catheter is threaded on the metal stylet, bent to an 80 degree angle 3 inches from the distal end. The laryngeal mirror is used and the catheter is introduced into the trachea and the stylet removed. The catheter should lie about 2 inches above the carina, and no effort is made to introduce it into the primary bronchi. The patient closes his lips on the catheter and then is asked to sit on a flat top table adjacent to an x-ray tube stand, where the actual injection is done.

IODIZED OIL INJECTION

A series of positions is assumed as the injection proceeds which allows gravity filling of all bronchial subdivisions. These are outlined in the accompanying series of sketches. The side of the chest suspected of disease should be examined first. If both sides are under scrutiny, it is customary to fill the left side first. The iodized oil is injected at room temperature, as this minimizes alveolar filling.

Figure 2. Four cc. is run down the left primary bronchus into the dorsal divisional bronchus and the lower lobe segmental bronchi. The position is held for one minute.

Figure 3. Two cc. is run down the left primary bronchus and into the left upper lobe bronchus. The position is held for one-half minute.

Figure 4. One cc. is injected to insure filling of the lingula as it is brought into dependent position. After one-half minute 3 cc. is injected and the patient is placed in the position of figure 5.

Figure 5. The position is held for two minutes to fill the apical segments and the patient is turned into the position of figure 6.

Figure 6. This position is held for one minute to complete filling of the posterosuperior segment and the dorsal division and then changed to the position of figure 7.

Fig 1—Materials required

sulfate one-half hour beforehand is useful for its effect in controlling the cough reflex. Atropine, given with the morphine, decreases the amount of secretion and thereby enhances the efficiency of topical anesthesia and iodized oil distribution.

It is important to have the bronchi empty at the time of examination. Postural drainage accompanied by voluntary coughing and efforts to raise sputum three hours before injection is used to this end. Thereafter the patient should neither eat nor drink until three hours after the procedure. Unless the bronchi are cleared of secretion before the injection, the examination will be rendered unsatisfactory by spasmodic coughing due to poor anesthesia and by failure of iodized oil properly to enter and delineate secretion-filled areas. The oil should be introduced and the x-ray films taken in the same room. The induction of anesthesia and the introduction of a catheter can be done in an adjoining room if this procedure is desirable, but the patient should not be made to walk from one room to another after the oil has been injected, as loss of time or involuntary cough will cause the picture to be marred by alveolar filling.

² Baker, D. C., Jr: *Pneumography, Laryngoscope* 46: 673 877 (Nov.) 1936

Figure 7. This position is held for one-half minute to insure complete filling of the basal division and then changed to the position of figure 8.

Figure 8. This position is held for one-half minute and a lateral view x-ray film is exposed with the patient lying on a cassette holder and the x-ray tube 4 feet above the table top.

At this point seven minutes will have elapsed and 10 cc. of iodized oil will have been injected. Filling

These films are developed immediately and examined. Meanwhile the patient lies quietly on a table. If any exposures need to be repeated, that is done. If the

Figs. 2 to 10.—Positions held during injections of iodized oil.
Figure 2.

Figure 3.

Figure 4.

Figure 5.

Figure 6.

of the opposite side is begun immediately and is performed in a manner similar to that just described. The right middle lobe will be filled by positioning comparable to that used for outlining the lingula on the left side. At the end of the procedure 20 cc. of iodized oil and fifteen minutes will have been required.

The patient then moves off the table and stands before an upright cassette 5 to 7 feet from the x-ray tube, where four additional exposures are made. These are:

- (a) Posteroanterior.
- (b) Posteroanterior with Lyshom grid.
- (c) Right anterior oblique (fig. 9).
- (d) Left anterior oblique (fig. 10).

Figure 10.

films are found satisfactory, the patient is placed in the head-down position and urged to cough up the iodized oil.

DETAILS OF FILMS

Thin, over-all coating of the bronchi is preferable. Alveolar filling is to be avoided.

One good posteroanterior film will often give most of the information needed for diagnosis. The others are necessary for confirmation, for careful study of special segments and for assurance that necessary views for subsequent study will be available. One cannot reduce the number of films without risk of lacking essential information on an important case.

The first lateral film taken defines posterior and anterior branches of the suspected side and gives a picture of spatial relationships that cannot be had when both sides are filled because of overlying shadows. The grid film allows detailed study of areas that may be too dense to show in ordinary films, such as an atelectatic left lower lobe lying behind the heart. By means of the right anterior oblique position the left side is thrown forward into relief, presenting a view of the important lingula bronchus (fig. 9). A similar portrayal of the right middle lobe is accomplished with the left anterior oblique exposure (fig. 10).

CONTRAINDICATIONS

Cases of active pulmonary tuberculosis, acute lung abscess, intrinsic asthma and suspected tumor should not be investigated by means of iodized oil unless exceptional reasons exist for the procedure. The information as recorded by iodized oil films frequently may be more striking in these cases but rarely is it additional to that available from x-ray study alone. Spread of tuberculous infection has been observed after iodized oil injection, and retained oil complicates indefinitely the interpretation of parenchymal shadows. Asthmatic persons occasionally suffer acute respiratory distress following injections, and care should be exercised to inject only one side if iodized oil films are deemed essential for study of localized disease. A diagnosis of obvious bronchial tumor may be more clearly demonstrated to the uninitiated by means of iodized oil, but important incipient signs may also be hidden from the expert in a difficult early case. Careful fluoroscopy and films in expiration as well as inspiration are more valuable aids in such cases. Oil trapped behind an obstructing tumor is a hazard that should be avoided, as it may cause pneumonitis.

NOMENCLATURE

The problem of correctly naming the tracheobronchial subdivisions has become increasingly pressing as techniques of x-ray reading, bronchoscopy, bronchography and pulmonary resection have appeared and improved. A complete reexamination of the surgical anatomy of the subdividing pulmonary vessels and bronchi has been required with attention not only to details of structure but also to simplification and improvement in nomenclature in order to meet modern practical requirements. As early as 1889 Ewart,³ stimulated by the original work of Aeby, published a classic monograph on "The Bronchi and Pulmonary Blood Vessels." The prefatory paragraph is of historical interest:

These pages have a general purpose which extends beyond the limits announced in their title. They represent an attempt to remove the too prevalent impression that the field of pulmonary investigation, having yielded all its fruit, is henceforth likely to remain barren. Although advised, not long ago, by an eminent physician, to turn my attention to some other organ less "worked out" than the lung, I have found no reason to complain of my subject, and I may even succeed in showing that, so far from this being an exhausted territory, there remain

within it some districts almost unexplored. . . . Moreover, a suspicion has arisen in my mind that the present deficiencies in our anatomical knowledge (some part of which it will be my endeavor to fill) might perhaps be held responsible for the halting and spasmodic feature in the development of pulmonary surgery, contrasting with the steady progress made in the surgery of other organs.

Ewart's monograph was the first serious attempt to construct a systematic nomenclature of the air tubes. He presumed the lack of a system due both to lack of need for one and to lack of systematic study. Since his time the need for a uniformly accepted system has increased steadily, and the bronchial distribution has been made a subject for intensive systematic study by numerous authors, much of it of a high order.⁴ The present difficulty

arises from a plethora of names for each ramification and from an effort to carry into working charts such details and variations as might more suitably be confined to the fundamental works of reference. Troubles have arisen, therefore, both from complexity of the individual systems and from lack of agreement among them.

(Footnote 4 continued on next page)

In the belief that a simple terminology, acceptable to a majority of workers in the thoracic field, is a primary condition for successful study and continued advance in the subject, we are proposing a classification designed to meet the practical needs of internists, radiologists, bronchologists and surgeons. It is in no sense a new arrangement and new names are not recommended, as our first concerns are simplification and reduction of confusion. Personal investigation of material at the operating table and of fresh autopsy specimens over a five year period has furnished first hand knowledge for the task of synthesizing the terminology of the proposed system.

Fig. 12.—Left lung, lateral view: *As*, anterosuperior segment; *Ps*, posterosuperior segment; *Al*, anteroinferior segment; *La*, lateral segment; *D*, dorsal divisional segment; *LAI*, anterolateral segment of lingula; *AI*, anteroinferior segment; *LPm*, posteromedial segment of lingula; *Am*, anteromedial segment; *Pl*, posterolateral segment; *Pm*, posteromedial segment.

taken after injection of iodized oil. These films necessarily record on a single plane the projection of bronchi into myriad planes. Schematic representation of the bronchial tree by free-hand drawings may wander far from reality when one relies for accuracy on artists' impressions of spatial relationships. Therefore the diagrams used here are actual tracings from actual bronchograms of patients under clinical investigation (fig. 11 and the table). The proposal specifically omits the finer ramifications and subdivisions, the practical importance of which from the standpoint of diagnosis and therapy lie in the future. Working terminology for these finer tubes may be added to the present system whenever the need arises.

The term primary bronchus is suggested for the two divisions of the trachea as preferable to main, major, arterial or trunk. The classification according to lobes is obvious and follows the usage of all authors except Nelson.⁵

The peripheral marking of the lungs by fissures and septums is subject to considerable irregularity and variation in degree. For example, the right middle lobe frequently is scarcely demarcated from the

right upper lobe, while the dorsal division of the right lower lobe occasionally is separated by a distinct fissure from the basal division, and the lingular division of the left upper lobe shows wide variations in depth of fissures. These portions of the lung have special sig-

Structural Anatomy of the Lung

nificance both pathologically and surgically. Pulmonary tuberculosis occurs predominantly in the apical division. The lingula is involved in bronchiectasis in 80 per cent of the left lower lobe cases.⁶ The dorsal division of the lower lobe is a frequent site of putrid lung abscess.

Involvement of this same division by bronchiectasis is rare, even though the predominant site of bronchiectasis is in the contiguous basal division of the lower lobe. The ability to remove these portions surgically for localized disease has been demonstrated. The term division is proposed to indicate these surgically and pathologically important anatomic portions of lobes. Thus, the left upper lobe has apical and lingular divisions and each lower lobe has dorsal and basal divisions. The right upper lobe may be thought of, if desired, as having only an apical division, while the right middle lobe possesses no divisional substructure.

The identification of portions of divisions brings one to the smallest unit of lung tissue of practical diagnostic or therapeutic importance at the present time, the bronchopulmonary segment. This we define as a subdivision of the pulmonary lobe delimited by avascular, diverging planes which may or may not be indicated by complete or partial fissures. Its apex lies in the hilus and its base fills an area on the lung periphery. It is supplied by integral bronchi and blood vessels, which vary in the manner of origin and intercommunication with the hilus but are fairly constant in their end distribution.

The right upper lobe is considered to consist of four segments, named anterosuperior, posterosuperior, anteroinferior and lateral. The right middle lobe consists of anteromedial and posterolateral segments. The lower lobe has two divisions, dorsal and basal. The dorsal division requires no subnames at this time. The basal division is characteristically divided into posteromedial, posterolateral, anteromedial and anterolateral segments. The left upper lobe has two divisions, one the lingular and one the apical. The lingula divides into anterolateral and posteromedial branches. The apical division separates into segments in a similar manner to the right upper lobe.

A frequent cause of confusion has been the variations of the smaller bronchi in their arrangement, both with respect to point of origin and to number visible bronchoscopically. Sometimes, for instance, only two segmental bronchi are visible at the end of a lower lobe bronchus, and occasionally all four are clearly seen, but the underlying subdivisions into bronchopulmonary segments are maintained beyond the hilar variations. Dissections and injections have shown that the segments described, surrounded by planes of avascular tissue, uncrossed by bronchi or blood vessels beyond the hilus, are found with remarkable constancy in the periphery of the lungs. In the hilus the segmental integrity is lost in a maze of interlacing bronchi, arteries and veins, varying from case to case and thus far defying exact classification.

SUMMARY

Bronchography has become an essential diagnostic aid in the investigation of many thoracic problems. An accurate, complete, intelligently made bronchogram can reasonably be expected of any one who undertakes the procedure. A simple, almost uniformly successful technic which is suitable for general use has been developed.

An adequate, accepted bronchial nomenclature is lacking but hoped for by a majority of workers in the thoracic field. A terminology is proposed to meet the practical needs of internists, radiologists, bronchologists and surgeons. Simplification and reduction of confusion are hereby sought.

ABSTRACT OF DISCUSSION

DR. CHEVALIER L. JACKSON, Philadelphia: The importance of bronchography is universally recognized now, and most thoracic clinics require the mapping of all five lobes of the two lungs before an operation such as lobectomy or pneumonectomy is attempted, certainly before it is done for bronchiectasis. I agree with the great efficacy of the technic which Drs. Adams and Davenport have described. This technic is very similar to one that we decided was most convenient for our needs. Dr. Maurice Bonnier and I described that technic about four years ago before the American Bronchoscopic Society, and the description was published in the *Annals of Otolaryngology, Rhinology and Laryngology* for September 1937. We had a number of years

before that given up the use of the bronchoscopic method of instillation of iodized oil because the catheter method has many advantages. We do not find it necessary to use a swab application in anesthesia. We use a spray and instillation of anesthetic solution preliminary to the introduction of the catheter. The posturing of the patient has been beautifully illustrated by the authors. As was shown, however, it is necessary to change the posture according to the portion of the bronchial tree which we wish to fill. I think they are very ambitious to attempt to fill all lobes of both lungs at one sitting, but under the most favorable conditions that can be done. It is our practice to do the study in two sittings, mapping the more involved one first, and then at a second sitting a few days later, or a week later, mapping the other lung. It is very important to insist on the use of oblique films if the two lungs are filled at the same sitting. I am in full agreement with the relative contraindications that have been mentioned. These contraindications are relative and not absolute. In 1939 I had the pleasure of seeing Dr. Hardie-Neil demonstrate the "bronchopulmonary segments" with the inflation method, using the prepared specimen and inflating each segment separately with a little air bulb and glass catheter. Ever since I saw this demonstration, in Honolulu, I have been working along with Dr. Huber of our department of anatomy on this subject. The importance of the segmental bronchus and the bronchopulmonary segment is definitely established. The bronchoscopist and bronchologist deserve the credit of pointing out the importance of the anatomy of the bronchi and lobes in thoracic disease. A number of years ago the bronchoscopists and bronchologists began insisting on lateral films, even before the bronchographic studies became routine in the study of these cases. Now, with the recognition of the conception of the segmental bronchi and the bronchopulmonary segment a further practical advance has been made.

DR. LOUIS H. CLERF, Philadelphia: I am interested in the presentation of Drs. Adams and Davenport, particularly in the multiposturing of the patient during mapping of the individual lung. This is one of the great difficulties, namely, to get the iodized oil in the desired location; obviously the catheter method has simplified this. It is not readily accomplished by the bronchoscopic method. For that reason I have been employing the catheter method for some time, using the coudé catheter and in certain instances the Thompson catheter. I wish to ask what type of catheter the authors employ. The nomenclature that is suggested seems practical. After all it must be based on anatomic distribution of the bronchi. It is necessary that we all use a common language in describing the tracheobronchial tree so that internists, surgeons and roentgenologists will be able to interpret our findings.

DR. RALPH ADAMS, Boston: I am grateful to Dr. Jackson for giving credit to previous workers who have studied this problem, and much of their work has been of a very high order. Ewart in 1889 was the first to direct attention to this subject and wrote a classic monograph on it, which can now be obtained only with difficulty. Neil, Jackson, his co-workers, Baker and many others have contributed. The technic of anesthesia was not elaborated, as we believed it to be superfluous before this group. A number 16 ordinary urethral catheter is commonly employed by us. In a previous publication we discussed the merits of the Thompson catheter for serial selective bronchography, as may be employed for the limited or localized study of special segments in particular cases. The oil should be injected at room temperature rather than warmed, because this minimizes alveolar filling, which in turn allows better study of the bronchial pattern and reduces complications which might arise, such as pneumonitis. The nomenclature proposed has been submitted informally to a number of leading thoracic clinics through their chiefs of service, Drs. Graham, Alexander, Eloesser and Doley, and I hope that Dr. Clerf has considered it also to determine whether they would be willing to accept this proposal or to accept it with modifications which they might suggest. We hope that this proposal, or a modified one, may become commonly used.

INTRAVENOUS ANESTHESIA

PAUL W. SEARLES, M.D.

BUFFALO

The simplicity of administration and the lack of detrimental effects of the short acting barbiturates have tended to increase their value for intravenous anesthesia greatly.

The historical background for intravenous anesthesia began with the use of chloral hydrate in 1872 by Ore of France. Following this, a group in Petrograd first used hedonal (methyl propyl carbinol urethane) in 1905. The volatile anesthetics were then used. Ether was given in saline solution intravenously by Burkhardt of Germany in 1909, and chloroform also had a brief trial. In this country Noel and Scuttar first used paraldehyde for this purpose. A brief trial was given ethyl alcohol by Marin of Mexico City in 1929. Avertin with amylene hydrate, first used in 1929 by Kirschner in Germany, had but little intravenous use. None of these received general recognition for intravenous anesthesia.

The first barbiturate to be administered intravenously was somnifen, a mixture of barbital and dial, and was introduced in 1924 in France by Fredet and Perlis. This preparation was subsequently changed to barbital and alurate. Pernoston was introduced by Bumm in Germany in 1927 and is still being occasionally used. It was probably the best intravenous anesthetic to be used prior to evipal. Following this, sodium amytal was introduced in this country in 1929 by Zervas. Pentobarbital sodium (nembutal) was tried in 1930 and found to produce a prolonged postoperative sleep.¹ Evipal soluble was first used in Germany by Weese and Scharpff in 1932. Pentothal sodium was introduced by Lundy and Tovell² in 1934. There have been a few barbiturates, namely, soneryl, eunarcon, methyl luminal and thio amytal, which have been introduced in the recent years but which do not appear to have particular merit as intravenous anesthetics.

Thus far the short acting barbiturates evipal soluble and pentothal sodium have proved the most satisfactory agents for producing intravenous anesthesia. Pentothal sodium is more potent than evipal soluble and affords greater surgical relaxation.

During the last six years I have had the opportunity of personally administering over two thousand anesthetics with short acting barbiturates and to observe the use of these drugs by other anesthetists in a like number of cases.

INDICATIONS

It is my purpose to suggest that intravenous anesthesia with pentothal sodium and evipal soluble can be used in certain major as well as minor operations and to emphasize their advantage for the "poor risk patient."

Where the short acting barbiturates are used in certain types of major operations they should be given in conjunction with other methods of anesthesia such as avertin with amylene hydrate, local block or nitrous oxide-oxygen. Brain surgery at the Buffalo General Hospital has been performed for the last two years under a combination of anesthesia which consists of a

basal dose of avertin with amylene hydrate, an infiltration of the line of incision with 1:15,000 nupercaine solution and intermittent doses of sodium pentothal. Rarely is there more than 1 Gm. of pentothal solution required for the entire procedure, which may take from four to five hours. A three way stopcock is fitted to a continuous intravenous drip and serves to administer both the anesthetic and fluids as desired. If the airway is inadequate an intratracheal tube can be inserted. Oxygen can and should be administered. This combination of anesthetics is ideal for brain surgery and I think greatly reduces the element of shock.

The administration of pentothal sodium to supplement an abdominal wall block and splanchnic block in a gastric resection results in good surgical relaxation with a minimum of shock for the patient. The intravenous anesthetic is administered in conjunction with a continuous intravenous drip as described. The intravenous anesthesia relieves the pain that may be caused subsequent to locating and injecting the splanchnics and also makes it possible to close the abdomen without straining on the part of the patient. If the patient is allowed to regain consciousness during the major part of the operation, it is seldom that more than 1 Gm. of pentothal solution is required for the operation. Oxygen should be administered continuously during the operation.

Previous experiments³ on dogs led me to believe that the barbiturates possessed a tendency to protect the animal organism against shock. Seely, Essex and Mann⁴ found that the onset of shock was delayed in animals given sodium amytal anesthesia as compared with those given ether anesthesia. Subsequent clinical experience has substantiated this contention and we are now using pentothal sodium in order to prevent shock in the "poor risk patient." Individuals with severe anemia, debility or senility tolerate pentothal very well. Lundy and his co-workers⁵ state that "the site of destruction of this thiobarbiturate is not known definitely at this time. The drug leaves the blood stream within a few minutes of its introduction and its effects on most patients who have disease of the liver and kidneys does not appear to differ greatly from its effect on patients with normal organs. Therefore we do not feel that intravenous anesthesia is contraindicated when disease of the liver or kidneys is present but it is wise to exercise greater caution with its administration." We have found that the diabetic patient tolerates the short acting barbiturates very well and feel that some of the decrease in our mortality in diabetic amputations can be attributed to their use. Fractures in the old age group, especially those of the hips, are well handled under intravenous anesthesia. It is well to avoid the use of morphine in this old age group, as the incidence of pulmonary complications may be increased when it is used. It is also important that a light anesthetic should be used throughout the entire anesthetic period.

The greatest use of intravenous anesthesia is found in minor surgery in which profound muscular relaxation is not required. Thus in a great variety of procedures such as breast biopsies, rib resections, dilation and curettage, vaginal perineal repair, removal of painful dressings, reduction of fractures, skin grafts, cystoscopy, certain cases of prostatic resection and numerous opera-

tions of this character, intravenous anesthesia is satisfactory. Esophagoscopy and bronchoscopy can be satisfactorily performed under anesthesia with pentothal sodium, provided a fairly deep anesthesia is obtained before the insertion of the instrument. Preliminary cocaineization of the throat should be carried out.

Certain uses have served to broaden the field of intravenous anesthesia. An intravenous anesthetic is valuable as a preliminary to the induction of an inhalation anesthesia to eliminate the fear which some patients have of a face mask. Likewise the pain experienced by some patients in the performance of certain local or regional blocks can be eliminated by preliminary administration of pentothal sodium. This method also can be used successfully to prolong spinal anesthesia or to prevent the accompanying nausea. However, the intravenous administration of the barbiturate during spinal anesthesia should be done cautiously in order to avoid a decided drop in blood pressure or slowing of respiration. Intravenous anesthesia as a preliminary induction to nitrous oxide-oxygen anesthesia for dental extraction has proved satisfactory in our hands. The use of intravenous anesthesia as a means for eliminating the explosion hazard in the operating room is especially valuable when a cautery or an electrical appliance is to be used.

ADMINISTRATION

A preliminary medication of pentobarbital sodium, morphine and atropine can be given to advantage before the intravenous use of pentothal sodium. The morphine and pentobarbital sodium greatly decrease the amount of drug necessary to use, and the atropine minimizes the possibility of laryngeal spasm, coughing and hiccups.

The administration of pentothal sodium is accomplished by the intermittent injection of a 2.5 per cent solution of the drug. My technic consists in a preliminary test dose of 1 to 2 cc. of the pentothal sodium solution to determine the relative tolerance which the patient has for the drug and also to prevent any danger of giving too large a dose on induction. This inductive tolerance varies greatly with each patient. I have found that as little as 2 cc. of a 2.5 per cent solution produced sufficient anesthesia in a debilitated patient to perform a complete amputation of an arm, while in other cases 1 Gm. of pentothal sodium failed to render the patient unconscious. After the preliminary injection has been accomplished the patient is asked to count, and while he is counting 1 to 2 cc. of the solution is injected at intervals until the patient is unconscious. The presence of surgical anesthesia is elicited by the lack of response to painful stimuli. Further small doses are injected when the anesthesia becomes too light.

Overdosage results in imperceptible respirations and later cessation of respirations accompanied by the development of cyanosis. Treatment consists in stopping the administration of the intravenous anesthetic, establishing an airway and performing artificial respiration. Oxygen and carbon dioxide should be administered and respiratory stimulants such as nikethamide, metrazol or picrotoxin should be injected intravenously in sufficient dosage to obtain a stimulation of respiration.

CONTRAINDICATIONS

The administration of large doses of these short acting barbiturates should be avoided because of the possible sequelae, such as a long postoperative depression or in some cases the occurrence of toxic symptoms manifested by an elevation of temperature or a rash. The dose can always be decreased when necessary by supplementing the intravenous anesthetic with other types of anesthesia.

It is well to avoid the use of intravenous anesthesia in patients with a cardiac history. This is especially true in patients suffering from dyspnea, whether it is of cardiac or of pulmonary origin. Pentothal is not always a good anesthetic for children under 10 years of age because of their small veins and because of the greater need for oxygen. However, if oxygen is administered to the child in conjunction with the intravenous anesthesia and great care is taken not to produce a profound anesthesia, pentothal sodium will prove satisfactory. Operations about the nose and throat should not be done under intravenous anesthesia unless blood or mucus can be cleared from the passageways and an efficient airway maintained at all times. The use of pentothal sodium in a patient who is receiving a drug containing sulfur is debatable, as there may be a cumulative effect. Evipal soluble can be used without fear of administering too much sulfur.

SUMMARY

The use of short acting barbiturates is not confined to minor operations. Small doses of pentothal sodium given intravenously will produce satisfactory anesthesia for major operations, provided other methods of anesthesia such as avertin with amylene hydrate, local block or nitrous oxide-oxygen is used in combination with the intravenous anesthesia. Pentothal sodium may be used to advantage for the "poor risk patient" because of the protective action against shock which is exerted by the barbiturates. Owing to the ease of administration and the type of anesthesia produced, the short acting barbiturates have become the anesthetics of choice in numerous other surgical procedures.

ABSTRACT OF DISCUSSION

DR. ROLLAND J. WHITACRE, East Cleveland, Ohio: The widespread use of intravenous anesthesia with the short acting barbiturates has made it necessary to advance certain definite recommendations for their use. Dr. Searles has performed a valuable service in clearly setting forth the scope of usefulness of intravenous anesthesia as well as its contraindications. I should like to emphasize the importance of the conservative use of these short acting barbiturates. By conservative I refer not to the number or variety of cases but specifically to the amount of drug used in each case. Without a doubt large doses of these drugs increase the incidence of untoward complications. Likewise technical skill, although undeniably important, is not sufficient reason for advocating the routine use of unsupplemented intravenous anesthesia with the short acting barbiturates. Dr. Searles has indicated numerous instances in which intravenous anesthesia may be used to advantage in conjunction with other agents. Undoubtedly, this method of using minimal doses of pentothal sodium or evipal will be found to be valuable in still other surgical procedures. During the past few years my associates and I have used pentothal and nitrous oxide successfully in many of our cases undergoing thyroid surgery. With premedication, usually not more than 0.5 Gm. of pentothal is required for the entire procedure. It has been demonstrated that the use of dilute solutions of pentothal sodium materially increases the margin of safety of this method of anesthesia. It has been our experience that a 2.5 per cent solution and, on occasion, a weaker dilution of pentothal sodium is adequate to produce satisfactory anesthesia. A suitable method of supplying oxygen to the patient should always be available whenever intravenous anesthesia is administered. The advantage of pentothal sodium for major operations and poor risk cases is more apparent when minimal doses are used and, as Dr. Searles has pointed out, this is often accomplished by using pentothal sodium in conjunction with other agents.

DR. GEORGE J. THOMAS, Pittsburgh: With regard to the use of intravenous narcosis in combination with a continuous intravenous drip of solutions, patients receiving physiologic solution of sodium chloride or dextrose in combination with

pentothal sodium make a better recovery and show less toxicity to the anesthetic agent. The anesthetic and the supplemental fluid can be given through the same needle by the use of a manifold. The use of oxygen continuously is important and should not be overlooked. Dr. Searles stated that the diabetic, the anemic and old persons tolerate pentothal sodium surprisingly well. I too have found this to be a fact, provided the anesthetic agent is supported with an analeptic stimulant. It was mentioned that esophagoscopies and bronchoscopies can be satisfactorily performed under pentothal sodium, provided the throat is well cocaineized and deep anesthesia is obtained before intubation is attempted. I find that the provisions he mentioned are very important for a satisfactory anesthetic when nasotracheal or orotracheal tubes are used. Dr. Searles mentioned the contraindication in heart disease. My associates and I made an extensive electrocardiographic study of patients under pentothal sodium anesthesia and failed to observe much of any deleterious effect on the myocardium or the conductive system of the heart. Therefore I believe that in only the severe type of myocarditis should pentothal sodium be considered contraindicated. We have found pentothal sodium exceptionally useful in eye surgery. I attribute our success in the use of pentothal sodium in this type of surgery to our preanesthetic preparation of the patient. The occasional sneezing that we previously experienced in eye surgery has been absent. The instillation of cocaine in the eye preoperatively cocaineizes, via the nasolacrimal duct, the delicate and sensitive nerve endings of the nasal mucosa.

DR. JAMES YANICK, Hornell, N. Y.: It has been my experience with intravenous pentothal sodium anesthesia that minor operations, such as lacerations and cuts, require far more anesthesia than is required to relax the abdomen. It has been shown by workers at Cornell University Medical College that moderate amounts of barbiturates increase the sensitivity of the skin to pain, and pentothal sodium is a barbiturate. My observations with pentothal sodium anesthesia confirm their findings. We have a couple of good rapid surgeons by whom all uncomplicated appendixes are removed routinely under pentothal sodium. I have found that unless a saline drip is used the needle will clot up with blood, because so little pentothal sodium is used. After one has given enough pentothal sodium to desensitize the skin so that the incision can be made without the patient moving, one doesn't have to give another drop and one will have relaxation of the abdomen. Of course, if it is decided to do an exploratory or a prolonged operation, one can always shift to another type of anesthetic. Actually, appendectomies or abdominal operations of less than an hour, lower abdominal operations, require far less pentothal sodium than is required in repairing a 4 or 5 inch laceration from a cut from glass or an automobile accident. The first time one gives pentothal sodium, when a regional block is used, watch the reflexes of the patient very closely. So little is used that one cannot believe that the patient is anesthetized. I know that the first time I gave it for a herniorrhaphy with regional block anesthesia, when the patient was rather restless and uncooperative although the regional block was excellent, the small amount of pentothal sodium consumed where the skin was already desensitized was really marvelous.

DR. HAROLD D. GREEN, Cleveland: I should like to ask the author if he has had any experience with chloralose A. We have been using it in the Department of Physiology at Western Reserve for two or three years and have found that in animals it is a very satisfactory anesthetic. It acts fairly rapidly yet not quite so rapidly as evipal. The animals have apparently a higher blood pressure and withstand operation better, and it is our impression that we can withdraw more blood from an animal before his blood pressure drops to shock level than we can with some of the other barbitol anesthetics.

DR. F. M. SUMMERVILLE, Oil City, Pa.: One doesn't find any deaths recorded, or practically none, but if one meets the fellows in the hall they can tell of a number of deaths. Ten different ones have told me about such deaths since I have been here. I should like to hear something about the deaths from intravenous anesthesia.

DR. PAUL W. SEARLES, Buffalo: I am very grateful to the discussers for bringing out certain points that I was unable to cover because of the time allotted and for enlarging on certain points, especially the contraindications, and the use of continuous oxygen throughout long operations. Dr. Whitacre emphasized the importance of the administration of small doses of pentothal sodium. Only by giving many of these intravenous anesthetics can one determine how small a dose will prove to be satisfactory. Of course, after the surgeon becomes accustomed to the use of intravenous anesthesia, a little movement now and then on the part of the patient is not too objectionable. It is important with administration of intravenous anesthesia in long operations that a patent needle should be maintained. Dr. Thomas emphasized the administering of pentothal sodium in conjunction with saline solution. I think that the manifold apparatus which he uses is very satisfactory. Intravenous anesthesia has been found to be a safe anesthetic when properly administered by a trained anesthetist. In answering the question tendered by Dr. Green, I do not believe that chloralose A has been used on human subjects. As to the deaths from pentothal sodium, I want to say that I have never had a patient die from the administration of pentothal sodium. I find that, when an overdose has been administered, the effects can be counteracted by giving artificial respiration and oxygen. If contraindications are carefully watched, the percentage of deaths will compare favorably with other types of anesthesia.

SPONTANEOUS CONVULSIONS FOLLOWING METRAZOL TREATMENT

ERICH LIEBERT, M.D.

ELGIN, ILL.

Opinion regarding the occurrence of epileptic convulsions in cases of uncomplicated schizophrenic psychosis is divided. While Kraepelin, Bleuler and Marchand reported that convulsive seizures not infrequently may be observed during the course of a schizophrenic psychosis, especially in catatonic patients, other authors have expressed the opinion that epileptic convulsions are extremely rare. The latter view has been expressed especially by Vorkastner¹ and by Strauss and Steiner,² who critically reviewed the literature on the subject. According to them the number of confirmed reports on epileptic convulsions in cases of dementia precox is extremely small, especially if strict criteria are applied in the evaluation of the various forms of attacks which may accompany a catatonic psychosis. If one demands the presence of pupillary disturbances, clonic-tonic movements and pathologic reflexes to indicate the epileptiform character of a seizure, the number of cases of dementia precox with attacks becomes extremely small.

Strauss and Steiner found in a group of 6,000 patients whose condition was diagnosed dementia precox only 20 in whom seizures had been reported. However, the evaluation showed that of these 20, in only 1 could the authors be certain of their epileptic nature. Recktenwald³ reported 4 cases of schizophrenia complicated by convulsions. In 1 the attacks seemed to be of a hysterical character; autopsy revealed in another a meningioma and in a third cerebral arteriosclerosis.

In the Elgin State Hospital, with a population of 2,564 patients with a diagnosis of dementia precox,

From the Elgin State Hospital and the Department of Nervous and Mental Diseases, Northwestern University Medical School.

Read before the Section on Nervous and Mental Diseases at the Ninety-Second Annual Session of the American Medical Association, Cleveland, June 6, 1941.

3. Recktenwald: *Epilepsieartige Krampfanfälle im Verlaufe der*

convulsive seizures are rare. In 2 such patients autopsy revealed intracranial neoplasms, a supracellular cyst in 1 and in the other a dermoid cyst of the pineal body. In a third patient, who died during his first epileptic status after a stay in the hospital of ten years, autopsy revealed an acute swelling of the brain. The statement made by the authors that "epileptic seizures are extremely rare in cases of schizophrenia, if they occur at all," is therefore in agreement with our own observations.

However, during the last two years the number of epileptiform attacks in schizophrenic patients seems to have increased. Within a relatively short time my associates and I have seen in the hospital 7 patients in whom repeated epileptiform seizures could be observed, while concerning an eighth patient, released from the hospital, the family reported attacks of unconsciousness. It was noted that all these patients, none of whom had ever had any convulsive disorders before, had undergone a series of metrazol convulsions and that the spontaneous seizures had started some time after the cessation of metrazol therapy. Concerning none of these patients except 1 reported on by the family and not directly observed by a physician was there any doubt as to the epileptic character of the convulsion.

Slow four per second discharge of high amplitude (patient B. R.).

The seizures occurred suddenly, without any premonitory symptoms, but not before several months had elapsed after the cessation of the metrazol treatment. The sequence of events is illustrated in the following case.

B. R., a woman aged 25, was admitted to one of the state hospitals in 1938. At admission it was stated that she had always been somewhat peculiar, although she was not considered psychotic until September 1938. At that time she complained that her body was deteriorating and that she was going to fall apart. She felt that people had been talking about her. Because of the symptoms she presented, the diagnosis of dementia precox of the hebephrenic type was made and metrazol treatment advised. The patient apparently improved; she expressed a desire to return home and had some insight into the fact that she had been mentally ill. In February 1939 she was paroled after a six month stay in the hospital. Fifteen months later, in May 1940, she suffered her first spontaneous convulsion. She fell suddenly to the floor, bit her tongue and foamed at the mouth; she did not regain consciousness for about five or ten minutes. The convulsive seizures at first repeated themselves at infrequent intervals, but they became more numerous and more severe; so that it was necessary to hospitalize the patient again, this time not because of the psychosis but because of the numerous epileptic attacks. Neurologic examination showed her to have strikingly increased deep reflexes, a positive Hoffmann reflex on both sides but no evidence of any involvement of the cranial nerves. Exami-

nation of the spinal fluid revealed a cell count of 3, negative Pandy and Ross-Jones reactions, a colloidal gold curve of 1110000000, a quantitative protein estimation of 32 per cent and a negative Wassermann reaction. A roentgenogram of the skull did not reveal any evidence of increased intracranial pressure or any other pathologic condition.

During her stay in the hospital the patient had a number of convulsions characterized by sudden loss of consciousness, tonic-clonic movements and dilatation and fixation of the pupils. During these attacks she sustained several severe injuries. There was no doubt as to the epileptic character of the seizures, which were controllable only by phenobarbital. In discussing her sensations before an attack she stated that some of the seizures began with a short aura. According to her own description: "I have a sensation like I am going to have a treatment of metrazol." She described also a feeling of tenseness on the left side of her face followed by dizziness and a disagreeable sensation in the epigastrium.

Other patients on whom information has been included in the accompanying table presented the same sequence of events. Eight are listed, ranging in age from 22 to 40. All except 1 had a diagnosis of dementia precox of one of the various subtypes, and all underwent a course, some patients several courses, of metrazol treatment. None had a history of a convulsive disorder

at any time, nor was there evidence of any convulsions or other epileptic phenomena prior to the use of metrazol, although some patients had been under close observation in the hospital for many years. There was no hereditary tainting. Roentgen examinations, some performed with air filling, did not reveal any evidence of a gross intracranial lesion which might be responsible for the occurrence of epileptiform seizures.

The spinal fluid examination, which included the colloidal gold test, qualitative and quantitative

protein determinations, cell counts and sugar and sodium chloride determinations, gave negative results.

As can be noted from the table, the convulsions occurred at least several months after the cessation of metrazol treatment. The interval ranged from three months to two years. Further treatment had been given in only 1 case, in which convulsive shock therapy was followed by a course of induced hypoglycemic states.

The convulsions observed were uniformly of the grand mal type, characterized by sudden loss of consciousness, severe generalized tonic-clonic movements and pronounced dilatation of pupils which did not react to light. Babinski's or Gordon's reflex was temporarily present shortly after the cessation of the seizure. Neither in symptoms nor in duration did the attacks differ from the disorders seen generally in grand mal epilepsy. Only 1 patient described an aura. No definite information was obtainable from the other patients, who were too uncommunicative. The electroencephalograms of these patients showed a large variety of the changes which are usually seen in epileptic disorders and which have been described in detail by Levy, Serota and Grinker⁴ as occurring in some of their cases after metrazol treatment.

4. Levy, N. A.; Serota, H. M., and Grinker, R. R.: *Electroencephalographic and Clinical Studies Following Metrazol and Electrically Induced Convulsive Therapy of Affective Disorders*, read before the Illinois Psychiatric Society in March 1941.

COMMENT

In 8 cases in which the diagnosis was dementia precox spontaneous convulsions occurred. The attacks started some time after the cessation of metrazol treatment. Although the 8 patients comprise only a small percentage of the schizophrenic population and of the metrazol-treated patients, it is noteworthy that the attacks occurred only in patients who had been treated with metrazol. No other etiologic factor could be discovered which might have been held responsible for the convulsions.

That paroxysmal electric dysrhythmias may be observed for several months after even a few injections of metrazol was reported by Levy, Serota and Grinker. These authors found changes in the electroencephalograms of 50 per cent of treated patients and in those of the more severely affected patients with epileptoid disturbances of the brain. Electric potentials developed characterized by three per second waves, bicuspid and tricuspid waves, spike and wave formations and substantially increased amplitude. Spontaneous epileptic convulsions were not observed by Grinker and his co-workers in their metrazol series. Read⁵ briefly

In the evaluation of our material, two facts seem to be outstanding. First, it took a considerable period—at least three months but mostly more than twelve months—before a spontaneous convulsion could be observed. Regarding this observation, one might think of the reports by Weil and his co-workers,⁹ who showed that in patients who had died several months after the cessation of metrazol treatment an extensive proliferation of the glia was present, involving astrocytes and microglia. These changes were similar to those found in experimental animals by the same authors. Although there was no direct relationship between the time elapsed after the cessation of treatment and the severity of the gliosis, there were well defined individual differences in the responses to the treatment. One might be inclined to link these facts together and to surmise that in cases in which spontaneous epileptic seizures develop the scar formation in the brain tissue is responsible for the lowering of the convulsive threshold. Neuronic alterations were observed also in his patients by Weil and have been observed by many other authors in patients who had died after metrazol convulsions. Grinker, in discussing a case of spontaneous convulsions

mentioned the fact that spontaneous convulsions were observed some time after metrazol treatment; his case was included in this study. Another case was briefly described by Hartenberg.⁶

The question of the mechanism for the production of the spontaneous convulsions arises. It is a common saying that one fit always disposes toward the next one. However, the epileptiform convulsions due to an acute intoxication are usually not followed by chronic epilepsy. Up to the present only two substances, absinth and lead, have been known to cause epileptic convulsions even a long time after their use has been discontinued. Magnan,⁷ who studied this effect of absinth extensively, reported several cases of chronic epilepsy traceable to the use of absinth. Since oil of wormwood when given intravenously produces convulsions similar to those obtained with metrazol, one might be inclined to suspect a similar action for the two substances. Discussing the action of lead and absinth, Muskens⁸ surmised that "in such cases the threshold is lowered or the resistance of the patient has been so completely broken down that the ordinary sequence of daily life is sufficient to provide the stimulus for the succeeding fits."

after electric shock treatment, expressed the opinion that the neurons had been damaged to such a degree that ordinary stimuli might produce a convulsive seizure. This explanation might hold true for the spontaneous convulsions following metrazol therapy. Although the neurologic examination in our cases did not reveal any definite pathologic changes, a pathologic functioning of the brain was indicated by the electroencephalogram.

The second fact which seems to be of importance is that the initial dose of metrazol necessary for the production of a convulsion was low—lower than that for the average patient receiving metrazol treatment. One might think that our patients, although they had not had any epileptic seizures before treatment, had a convulsive threshold which could easily be broken down by the administration of metrazol. This might indicate that constitutional factors play a part. Before the administration of metrazol the convulsive threshold was high enough to avert epileptic seizures, but the pathologic alterations produced by the treatment lowered this threshold to such an extent that now ordinary stimuli were sufficient for the production of a convulsion. Since autopsy reports on our patients are not yet available, a definite correlation between the pathologic changes and the clinical picture still needs to be obtained.

SUMMARY

In 8 patients epileptic convulsions developed three to twenty-four months after the cessation of metrazol treatment.

None of these patients had had any convulsive seizures prior to the metrazol treatment, although they had been observed in the hospital for many years.

As epileptic seizures in cases of dementia precox are extremely rare, the production of the spontaneous seizures was thought to be due to the metrazol therapy, metrazol being able to cause spontaneous convulsive seizures, possibly in the same manner as do absinth and lead.

In using metrazol in the treatment of functional psychoses, therefore, one should take into account the possibility of the production of spontaneous epileptic seizures even a long time after the cessation of treatment.

750 South State Street.

ABSTRACT OF DISCUSSION

DR. ROY R. GRINKER, Chicago: We should be grateful to the author for bringing the matter of late appearing defects following shock treatment to our attention. The evidence that has been gathered from electroencephalographic studies following shock treatment, whether by metrazol or electrically induced shock, is that the brain waves are pathologic for some time after treatment, showing a rhythm of three, four and six per second with large cusps of great amplitude and sometimes spike formations. It has been anticipated, as has been reported here, that many psychotic patients would eventually become epileptic through the use of shock therapy. It might be said that these individuals had the potentialities of developing epilepsy before treatment. It is unfortunate that brain waves were not taken before treatment so that they could be compared with those afterward. In my patients the curves were all normal before treatment. The statement might be made that in the schizophrenic psychoses the number of shocks given was usually far greater than in the depressions, and hence the excessive quantity may be responsible for the development of epileptic attacks. In my work I have found no correlation between the number of shocks and the characteristic abnormalities in the brain waves seen afterward. It is true that these waves gradually subside and the normal curve eventually returns. This problem brings us back again to the discussion of choice between rational therapy and the danger of long standing psychosis as against rapid relief of depression and anxiety with the signals attendant on varying damage to the brain. Does one wish to take a chance on producing rather severe brain damage or to wait in certain cases until the psychosis recedes and the patient becomes amenable to more rational psychotherapy? I cannot pass this opportunity to say that we are becoming less psychiatrists and more and more physical therapists. At one time I indicated that, with metrazol, psychiatrists hardly waited for the patient to take his clothes off before he was shocked, and now we learn from Dr. Myerson that it is not necessary to hospitalize a patient, that one can shock him in one's office, keep him there for an hour or two and then return him home. This I consider extremely dangerous, since before long such easily applied therapy will be appropriated by the inexpert and used promiscuously and indiscriminately. It is obvious that this method is less dangerous than lobotomy because recovery of memory does occur and electroencephalographic findings tend to return to normal. When one cuts the fiber pathways everything is gone and no regeneration of the central tissue is possible. After shock there is a possibility that the irritative effect of some of the acute lesions may disappear.

DR. ERICH LIEBERT, Elgin, Ill.: I only want to mention that in the last two months I have had 2 more cases in which spontaneous convulsions were observed after metrazol treatments had been given.

POIKILODERMA-LIKE CHANGES IN THE
SKIN FOLLOWING ARSPHEN-
AMINE DERMATITIS

REPORT OF TWO CASES

A. BENSON CANNON, M.D.

MARIE B. KARELITZ-KARRY, M.D.

AND

JEROME K. FISHER, M.D.

NEW YORK

For the past two years we have had under observation 2 patients with postarsphenamine dermatitis terminating in erythema, pigmentation, telangiectasia, atrophy and alopecia, a combination of symptoms which strikingly resembles those first described by Jacobi¹ at the German Dermatologic Congress in Berne in 1906 and named by him poikiloderma atrophicum vasculare. The body of literature on this subject is comparatively small, considering the fact that the disease has been known to the medical profession for thirty-five years. Since Jacobi's case approximately 160 others have been reported, most of them for confirmation of diagnosis before various local dermatologic societies. It is interesting to note that in only 4 of these cases was the poikiloderma or the poikiloderma-like changes in the skin regarded by the author as the sequels of a postarsphenamine dermatitis; these 4 all appeared in the foreign literature.

REVIEW OF THE LITERATURE

K. Pinter² reported the first case of this type before the Hungarian Dermatologic Society on Nov. 9, 1928. The patient, a woman aged 23, had received three series of neoarsphenamine injections, after each of which she had an attack of arsphenamine dermatitis. The first attack, which came on after she had received 4 Gm. of neoarsphenamine in 1926, subsided in about three months, leaving a brown pigmentation followed by telangiectasia, punctate hemorrhages, thinness of the skin and other appearances of poikiloderma.

Gruetz³ on Oct. 12, 1930 presented before the Society of Rhenish-Westphalian Dermatologists a woman of 40 whose skin showed poikiloderma-like changes which had followed a generalized arsphenamine dermatitis. There were numerous irregular pigmentations. The body and scalp hair had almost entirely disappeared. Histologic sections showed that there were pigment deposits in the papillary bodies and that the elastic fibers had changed into small, well defined bandlike zones parallel to the epidermis.

Grau Barberá⁴ cited the case of a man of 26 who was given eight injections of neoarsphenamine (totaling 4 Gm.) in treatment of a primary lesion. After the next to the last injection an itching, nonexudative, erythematous eruption was noted in the heavy folds of the skin of the elbows, axillas and knees. There was some desquamation. The patient was given two injections of a bismuth compound, after which the erythematous eruption became generalized and

From the Department of Dermatology, Vanderbilt Clinic, Columbia University College of Physicians and Surgeons.

persisted for five months, with itching and abundant desquamation accompanied by slight loss of hairs from the eyebrows. After the erythroderma had disappeared areas of reticular atrophy were seen, distributed over the whole body but most profusely over the skin of the abdomen, flanks, thighs and Scarpa's triangle. In the atrophic areas were islands of normal skin which were slightly hyperkeratotic and showed some purulent desquamation. The hyperkeratotic areas were more pigmented than the normal skin. The skin as a whole showed a slight wrinkling comparable to that found in patients with mild xeroderma. Finely branched telangiectases were found distributed regularly throughout. The anterior region showed pigmentation, with light reticulated hyperkeratosis. There was faint pigmentation in the inguinal folds and in places where the lesions were most abundant. The mucous membranes were also involved. Both clinically and histologically the patient presented the appearance of having poikiloderma.

Covisa and Bejarano⁵ reported the case of a woman aged 39 with a strongly positive Wassermann reaction who was given a total of 5 Gm. of neoarsphenamine and 2 Gm. of a bismuth compound. Before she received the next to the last injection of neoarsphenamine an erythematous eruption appeared, beginning in the flexure of the elbow and finally becoming generalized and exceedingly pruritic and exudative in type. The dermatitis gradually cleared, leaving a diffuse reticular eruption with alternate zones of erythema, pigmentation and atrophy, telangiectasia and in some places a furfuraceous desquamation.

Both the clinical and the histologic changes were consistent with those of classic poikiloderma as described by Jacobi.

Epstein's⁶ case, which he described as of an "unusual reticular fibroatrophyderma following arsphenamine dermatitis," might also be included here, since the changes which occurred are strongly reminiscent of poikiloderma, even though Epstein did not himself suggest any connection with that disease. After a course of neoarsphenamine injections the patient, a woman aged 41, had a typical generalized arsphenamine dermatitis which, when it subsided, left a peculiar atrophyderma over the portion of the neck which is exposed when a V-necked dress is worn. The skin over this area was thinned and inelastic. Numerous telangiectases were present. The surface was traversed by numerous keloid bands which intersected to form a network.

Histologic examination showed a thin epidermis, intracellular edema, fibrosis of the corium and some endarteritis. There were a few foci of round cells scattered throughout the cutis.

In these 4 instances of poikiloderma-like changes and the 1 of "atrophyderma" closely resembling poikiloderma the changes described occurred as a sequel to arsphenamine therapy. We found reported in the literature 4 other cases of poikiloderma-like changes, 3 of which were due to exposure of the skin to substances containing arsenic, while the fourth followed treatment with arsenic in a form other than arsphenamine.

Noguer-Moré and Grau Barberá⁷ described 3 cases of follicular pigmented exogenous toxicoderma occur-

ring in women engaged in occupations in which they came into contact with oily substances containing iron and arsenic, the parts of the skin affected being those which were directly exposed to the oily substances (hands, lower arms, face, neck and exposed parts of the chest). There was chronic or subacute inflammation around the skin follicles, with some tendency to hyperkeratoses and with hyperpigmentation or hypere-mic pigmented macules in uneven distribution. The pigment was partly clumped and partly arranged in a network. No atrophy was observed.

Von Leszczynski⁸ found poikiloderma-like symptoms in a man aged 35 who had received sixty-eight injections of an arsenical during the period 1916 to 1917 and more of the drug (in quantities not stated) from 1919 to 1920 for alleged pityriasis rubra; his skin showed changes typical of Jacobi's poikiloderma after exposure to wet and cold and, subsequently, to an explosion. Von Leszczynski expressed the opinion that the combination of shocks caused a later pituitary disease (insufficiency) and probably led also to the development of the cutaneous condition. He did not attempt to incriminate the arsenical in the causation of the condition, but it probably was of much more actual importance than the shocks which he stressed.

Nobl⁹ in 1935 gave an excellent comprehensive discussion of poikiloderma due to arsphenamine, but he did not cite any cases.

Only a comparatively small number of papers on the subject have found their way into print. In the American literature they have been particularly few, only eight articles (by Lane,¹⁰ Bowman and Clark,¹¹ Usher,¹² Taussig,¹³ Oliver,¹⁴ Keil,¹⁵ Guy, Grauer and Jacob¹⁶ and Hazel¹⁷) having appeared on the subject since Lane^{17a} introduced the first American case before the New York Dermatological Society on May 25, 1920. In view, therefore, of the comparative scarcity of reported cases of poikiloderma or poikiloderma-like changes following arsphenamine dermatitis we felt that it would be of interest to present our 2 cases, in which arsenic seemed definitely to be the active agent in the production of the cutaneous changes observed.

REPORT OF CASES

CASE 1.—G. V., a Puerto Rican woman aged 32, was admitted to the Vanderbilt Clinic in April 1937 with a generalized eruption and total alopecia of two years' duration.

The patient remembered no childhood diseases. Menstruation started at the age of 12 and was always regular and normal. She was married at 18 and had one child, aged 12 years, living and well. There had been one accidental abortion. At the time of the patient's admission to the clinic her husband was being treated in a tuberculosis sanatorium. (He died in 1938.)

Her first admission was to the obstetric department of a hospital because of pregnancy in November 1936, at which time a routine Wassermann test gave a strongly positive result (4 plus). She denied that she had had any initial or secondary syphilitic lesions. After she had received eight intravenous injections of neoarsphenamine and three intramuscular injections

Fig. 1 (case 1).—Extensive pigmentation, areas of depigmentation, atrophy, telangiectasia, especially of the cheeks, and extensive alopecia.

tions of a bismuth compound she had a generalized exfoliative dermatitis. In January 1936 she was referred to the gynecologic department because of a suspected abortion. Roentgenographic examination in April 1936 revealed the presence of a 6 month fetus. It could not be determined by roentgenogram whether the fetus was viable, although, because of the overlapping of the small bones and the distortion of the head, it was assumed that it was not. The patient, however, refused to allow the uterus to be evacuated.

At that time the skin showed little exfoliation, but there was a generalized thickening, with a papular eruption and almost total alopecia, and the skin had become much darker.

In February 1937 she visited one of the board of health clinics to continue antisyphilitic treatment, her chief complaint being impaired vision and excessive lacrimation. She was given five injections of sodium thiosulfate and was then transferred to the Vanderbilt Clinic.

Physical examination on admission to the clinic showed that she was well developed and fairly well nourished, weighing 110 pounds (49.9 Kg). The general physical examination revealed no pathologic changes except enlarged and cryptic tonsils. The eyes were essentially normal, the fundi healthy and the media clear, and there was no evidence of cataract. The neurologic examination was noncontributory.

The entire skin presented a remarkable picture of extensive deep brown to black mottled, pigmented areas, together with a fine network of telangiectatic blood vessels, atrophy and total alopecia (fig. 1). The skin over the face, neck, chest and scalp was more atrophic than that of the other parts and had a decidedly reticulated appearance, with numerous small

capillaries which appeared to be covered only by the thinned, atrophic, wrinkled skin. Over the skin of the abdomen near the umbilicus and on the upper posterior aspect of the right arm there were a number of pea-sized, papular, verrucous lesions. There was severe hyperkeratosis of the soles and heels and the sides of the great toes. A pea-sized cutaneous horn projected over the right eyebrow. The mucous membranes of the cheeks and the tongue showed extensive areas of leukoplakia and light brown to bluish pigmentation. The nails were not involved. Perspiration was not noticeable anywhere except on the palms and soles.

The blood count, examination of the urine, chemical examination of the blood and Aschheim-Zondek rabbit test all gave results within normal limits.

The arsenic content of the blood, determined at various intervals from 1937 to 1941, ranged from 0.005 to 0.21 mg per hundred grams of dry blood. The skin showed 0.003 mg. of arsenic per hundred grams of dried specimen. The arsenic content of the urine measured at one time 0.03 mg and on another occasion 0.08 mg. in a twenty-four hour specimen (670 cc.)

Spectrographic examination of the skin showed the presence of sodium, magnesium and iron, but no abnormal metallic constituents were noted.

Serologic tests of both blood and spinal fluid gave negative results.

The first intradermal test with old arsphenamine, which was made in April 1937, one year after the first appearance of the exfoliative dermatitis, produced erythema with infiltration and scaling within two weeks. After a month a nodule was formed and the erythema and scaling disappeared. The second test, made in 1940, four years after the development of the dermatitis, produced a 2 to 3 cm. area of dermatitis with a 1 cm. papule in the center.

Patch tests with old arsphenamine, made in 1938, gave negative results.

Fig. 2 (case 2).—Partial alopecia of the scalp.

Roentgenograms of the skull showed no abnormalities except calcification of the pineal body.

Histologic examination of a section from the abdomen showed severe hyperkeratosis. The epidermis showed some areas of atrophy and others of acanthosis. The corium was edematous and vascular and was the site of a chronic inflammation. Numerous chromatophores were seen. The histologic diag-

nosis was atrophy of the skin with keratosis and melanodermitis.

Another specimen of tissue consisted of a keratotic plug resting in an epidermal invagination. Beneath this plug the epidermis had undergone acanthosis. No malignant changes were noted. There were evidences of dyskeratosis and some changes in the granular layer, such as occur frequently in patients with verruca vulgaris. In the area of greatest change the melanin pigment had disappeared. The adjacent epidermis,

Fig. 3 (case 2).—Pigmentation, depigmentation, telangiectasia and atrophy of the chest.

however, was hyperpigmented. The corium beneath the lesion was the site of definite though not extreme chronic inflammation. The histologic diagnosis was arsenical keratosis.

From April 1937 to June 1940 the patient has received forty-two injections of sodium thiosulfate and twenty injections of bismo-cymol. She has also received liver extract, vitamin preparations and constitutional therapy as indicated.

Since she first came under observation in May 1937 her progress has been slow but gradual. The skin has become softer, and there is a sparse growth of hair in the occipital, axillary and suprapubic regions, but the other parts of the body are still entirely without hair. By June 1937 the hyperkeratotic plaques on the soles had cleared up and the skin had become lighter. In September the skin over the chest, back and arms had lost its reticulated appearance, the dark spots had entirely disappeared, the telangiectasia over the face was much less prominent than before and the scanty growth of hair on the parietal areas of the skull had improved. Black, pigmented, macular spots were still present on the thighs and buttocks. The leukoplakia of the tongue and the buccal mucous membranes had almost disappeared. By December 1937 the patient's eyesight had improved so much that she could read small print. About that time the verrucous lesions on the right arm and the left ear fell off spontaneously. In March 1938 the patient noticed that she perspired somewhat more freely than she had before. In May she underwent an operation for the removal of the fetus, which had been retained for more than two years. After operation her general health improved a great deal. In June the keratosis on the feet cleared up, but the verruca on the ear grew back. By November 1939 she had gained 10 pounds (4.5 Kg.) and felt and looked much better. The skin had become smoother and was of more normal color and texture, the atrophy was much less noticeable, and the veins on the face and chest were not so raised as before. In June 1940 new verrucous lesions appeared on the left arm, and a dark brown scaly plaque was seen on the upper portion of the left eyelid. At present the patient is feeling well. The skin on the body and the extremities is much softer and has lost practically all its spotted appearance. The growth of hair over the occipital portion of the skull is somewhat improved, although the rest of the skull is so nearly bald that the patient has to wear a wig. Her main complaint now is that because of her deficient perspiration she is unable to tolerate hot weather well.

CASE 2.—E. A., a German man aged 37, an automobile mechanic, was admitted to the Vanderbilt Clinic on Dec. 13, 1939 with a generalized eruption and alopecia of two years' duration.

The personal and family histories were noncontributory.

The patient had had none of the usual infectious diseases of childhood except a "lung catarrh." Eighteen years before, while he was in Brazil, he had had several attacks of herpes progenitalis, for which he had received only local treatment. He denied having had any sexual contacts at the time. In 1928 he had a recurrence of the herpetic lesions on the prepuce after intercourse. Two years later he received several injections of an unknown drug for "rheumatism." In December 1937 the blood showed a slightly positive Wassermann reaction, and he was given three intramuscular injections of a bismuth compound and three intravenous injections of nearsphenamine. After the third injection of nearsphenamine he had a severe generalized dermatitis for which he was treated with six intravenous injections of a strontium bromide preparation, without any improvement. The eruption became more severe and was accompanied by a great deal of oozing and swelling, particularly on the face, scalp and legs and around the eyes. In September 1938 the patient consulted another physician, who diagnosed his condition as a "generalized exfoliative arspenamine dermatitis of the severest type." He was given calcium gluconate in fairly large doses and a soothing ointment (type unknown). He received also four fractional doses of roentgen rays (100 r each) on his arms, wrists and hands.

Physical examination on admission revealed that the patient was well nourished, unusually well developed and muscular and weighed about 155 pounds (70.3 Kg.). The general physical and neurologic examination gave essentially irrelevant results, except to reveal a soft systolic murmur at the apex of the heart, not transmitted.

Examination of the skin showed generalized erythroderma, with partial alopecia of the scalp, eyelids and axillary and pubic regions (fig. 2). The skin of the entire body was dry and except on the hands and feet had a bluish red tinge. Across the chest it was reticulated and mottled, in some places showing a purplish and in others a brown pigmentation (fig. 3). The skin was atrophic and wrinkled, with a fine network of

Fig. 4 (case 2).—Section stained with hematoxylin and eosin, showing atrophy of the epidermis, loss of rete pegs and variation in the melanin content of the basal layer. Note the zonal edema, increased vascularity, moderate infiltration of mononuclear cells and scattered chromatophores in the upper layers of the cutis ($\times 140$).

telangiectatic blood vessels which gave a depressed appearance to certain areas. Numerous warty lesions were found in the axillas, on the thighs and on the lower part of the abdomen. There was severe hyperkeratosis of the palms and soles, and the buccal mucous membranes were spotted with leukoplakic areas and streaks. The scalp was atrophic and telangiectatic. Perspiration was noted on the face, hands, feet and knees only. The nails were not involved.

The blood count, chemical examination of the blood, urinalysis and Wassermann examination of the blood all gave results within normal limits.

Determinations of the arsenic content showed 0.055 mg. per hundred grams of dry blood, 0.008 mg. per hundred grams of dry skin, 0.045 mg. per hundred grams of dry stool (23.7 per cent solids) and 0.1 mg. in a twenty-four hour specimen of urine (1,470 cc.).

Coproporphyrin in a twenty-four hour specimen of urine (1,470 cc.) measured 0.01 mg.

Spectrographic examination of the skin showed no gold or bismuth present but showed silver, 0.0008 mg. per gram of dry tissue and 0.0003 mg. per gram of tissue as received.

Intradermal tests with neoarsphenamine made three years after the development of the dermatitis produced erythema and scaling within two days, a definite area of dermatitis after two weeks and in about a month a nodule which two months later had not yet become involuted.

Patch tests with various types of automobile greases and oils gave negative results.

Roentgenographic examination of the chest showed no abnormalities. Stereoroentgenograms of the skull revealed slight calcification of the frontal bone and calcification of the pineal body. The sella turcica and the rest of the skull were normal.

Histologic examination of a section from the abdomen showed that the epidermis was severely atrophic in some places. There was decided hyperkeratosis. The granular layer was extremely thin, being for the most part represented by a single line of cells. There was severe edema throughout. The melanin content of the basal cell layer varied greatly (fig. 4). The underlying corium was extremely edematous. The vascular channels were increased in number. There was a considerable increase in spindle-shaped cells. A moderate inflammatory reaction could be seen. These changes were most striking in the corium just beneath the epidermis. The deeper portions of the corium, however, were relatively free from pathologic change. Large numbers of chromatophores were found in the areas in which the melanin of the basal layers was most depleted. The elastic fibers of the superficial portions of the corium showed advanced disintegration (fig. 5). Sections stained by Fontana's method brought out strikingly the great variation in quantity of melanin in the epidermis and in the number of chromatophores within the corium (fig. 6). The histologic diagnosis was arsenical keratosis.

Histologic examination of a warty lesion from the left thigh disclosed that the skin in that region had undergone extensive

the corium by a mass of epithelial cells. The cutis was the site of a severe inflammatory reaction, with dilated blood vessels, infiltration of lymphocytes and plasma cells and proliferation of fibroblasts. Melanin, which was conspicuous in the basal layer of the uninvolved epidermis, had disappeared entirely from the verrucous epidermis. The lesion was evidently a keratosis with characteristics of verruca vulgaris.

Fig. 6 (case 2).—Section stained by the Fontana method, showing variation in the quantity of melanin ($\times 188$).

From January to November 1940 the patient received thirty-five intravenous injections of sodium thiosulfate. At present the skin is softer, and the keratotic lesions on the abdomen and the left thigh have become smaller and somewhat involuted. The alopecia, atrophy and telangiectasia are still present, but they are all much less noticeable than when the patient was first seen. There is only a slight pigmentation present in widely scattered areas. The patient's general health is good.

COMMENT

The 2 cases of poikiloderma-like changes in the skin presented here are identical as to the history and development of the dermatitis, the main difference being in its degree. In both an acute inflammatory exudative dermatitis appeared after arsphenamine treatment for syphilis. The symptoms of this dermatitis corresponded in every respect to those of an arsenical dermatitis, and the condition was so diagnosed and the patient so treated. Instead, however, of the dermatitis disappearing in the course of time, leaving no after-effects, as an arsphenamine dermatitis usually does, the skin sustained apparently permanent damage, becoming extensively pigmented and showing both light and darker colored patches of diffuse atrophy mingled with a dark red network of telangiectatic blood vessels which stood out prominently, giving the entire skin a reticulated and marmorated appearance. The skin within the network was wrinkled, thin and atrophic. There was well defined thickening of the skin of the palms and soles, especially around the heels and the great toes. On the abdomen, the upper arms and the anterior axillary folds there were pea-sized dark brown papillomatous growths.

The mucous membranes of the mouth and tongue in both cases showed widespread leukoplakic streaks or lines, a condition frequently found in greater or less degree in cases of chronic arsenic poisoning.

One of the most striking features in both patients was the alopecia, which was total in the more severely affected one (G. V.) and was accompanied by a decided atrophy of the scalp, particularly over the vertex. The alopecia in the man (E. A.) was only partial, there being a few thin clusters of hair scattered over the scalp, eyebrows and eyelashes and the axillary and suprapubic regions. Undoubtedly the alopecia can be

Fig. 5 (case 2).—Section stained by the Taenzer-Unna orcein method, showing disintegration and disappearance of elastic fibers in the upper layers of the cutis as a result of inflammatory changes ($\times 140$).

hyperkeratosis and acanthosis. There was only slight parakeratosis, particularly evident over the outward projections of the epidermis. The granular layer had increased remarkably in width. Many of the granules had a coarseness such as is seen in cases of verruca vulgaris, and the individual cells were somewhat swollen. This striking change was most pronounced in places where the acanthosis had resulted in penetration of

explained by the atrophy of the scalp. Hence it too may be regarded as more or less permanent. That it actually is may be seen from the fact that although more than four years have elapsed since alopecia developed in the first patient (G. V.), the scalp is still almost totally bald, except around the occipital region, and the vertical portion still presents a smooth, shiny, light to whitish, atrophic appearance. The body hair, too, shows only a sparse growth. The alopecia of the second patient (E. A.) is also apparently permanent, although recently he reported that hair is beginning to grow on the forearms.

Of the numerous laboratory studies made of these 2 patients only two or three need to be mentioned. The arsenic content of the blood, urine and skin was for the most part normal or high normal, only one of the several determinations made giving results at all high (0.21 mg. in the blood, in case 1). The comparatively normal figures for arsenic can probably be explained by the fact that a long interval (more than two years in each case) had elapsed between the institution of arsphenamine therapy and our arsenic determinations, so that there was ample time for most of the arsenic to be eliminated by the organism.

Roentgenograms of the skull showed slight calcification of the frontal bone in 1 patient (E. A.) and calcification of the pineal gland in both patients. We have been able to find only 1 other instance of calcification of the pineal gland in a patient with poikiloderma, namely that reported by Montgomery and O'Leary¹⁸ before the Chicago Dermatological Society on Oct. 21, 1931. Whether or not this condition has any significance in cases of poikiloderma or poikiloderma-like changes in the skin we are not prepared to say, but in view of its rarity we feel that its presence in both our patients is interesting. The calcium-phosphorus ratio of the blood of both patients was entirely within normal limits, and no other evidences of calcification were revealed by either clinical or laboratory examination.

Treatment of both patients prior to admission to the Vanderbilt Clinic had consisted mainly in attempts to eliminate arsenic by means of calcium and sodium thiosulfate injections and the use of soothing applications. Our treatment consisted of calcium and sodium thiosulfate injections, use of a high caloric diet, administration of vitamins by mouth and for 1 patient (G. V.) removal of the petrified fetus. While the skin of both patients has shown a gradual if slow improvement, the atrophy remains, together with some telangiectasia; in both there is alopecia, almost total in the woman and partial in the man. The pigmentation has almost entirely disappeared, and the skin has practically regained its normal color. However, even though the skin may continue to improve it is probable that the atrophy and alopecia are permanent.

When we consider the clinical features of our 2 cases of postarsphenamine dermatitis—the atrophy, telangiectasia and pigmentation, the marmorated and reticulated appearance of the skin, the alopecia and the symptoms of general weakness and muscular pain—and compare them with those in the case of poikiloderma atrophicans vasculare described under that name for the first time by Jacobi¹ in 1906, we are immediately impressed by the clinical similarity of the 3 cases. Histologically, too, our 2 cases bear a close resemblance to Jacobi's,

in which the main features were atrophy and hyperkeratosis of the epidermis; interstitial and parenchymatous edema and infiltration, chiefly perivascular in type; decided thinning of the granular layer; pigmentation scattered through the upper cutis, varying to a decided degree in different locations, and severe disintegration and deficiency of the elastic tissue in the superficial portions of the corium. Unlike Jacobi's case, however, in our cases there was a definite history of arsenic intake, and the dermatitis which initiated the present poikiloderma-like changes had all the characteristics of typical arsenical dermatitis. The histologic changes too suggest an arsenical keratosis.

Another feature of our cases which should be noted is that both the patients had a history of an earlier toxic condition: The first patient (G. V.) had undergone a pregnancy with subsequent retention of the fetus in the first three years of observation, while the other (E. A.) had a history of "rheumatism" which was treated by three injections of some unknown drug. The question therefore presents itself whether some other factor, perhaps a toxic one, may not have played a part along with the arsphenamine in causing the remarkable cutaneous changes or whether we are justified in assuming that these changes resulted from the arsphenamine alone. The toxic origin of poikiloderma and poikiloderma-like changes has been suggested before. It will be remembered that Ehrmann¹⁹ in discussing Jacobi's first case suggested the possibility that the condition might be a toxic erythroderma; and there have been various other authors since who have favored the theory of a toxic origin. The question of the relative responsibility of toxic conditions and a previous arsenic intake for the development of the poikiloderma-like changes in our cases is a debatable one. Certainly although arsphenamine dermatitis itself occurs commonly, poikiloderma-like changes following it are comparatively rare, an assertion that is substantiated by the limited number of such cases reported in the literature. Hence it would seem logical to believe that it is the arsphenamine rather than the toxic factors which should be incriminated in the 2 cases reported here, though it is entirely possible that toxic conditions may also have contributed, secondarily, to the development of the poikiloderma-like changes.

Jacobi of course thought that the disease which he described was an entity distinct from any other disease described hitherto. While our cases bear a strong resemblance to the one reported by Jacobi, we feel that the changes do not represent a type *sui generis* but were due to an exogenous factor, namely arsphenamine. It will be remembered that Oppenheim,²⁰ in his masterly discussion of poikiloderma in Jadassohn's "Handbuch," remarked that this disease falls into three types: (1) the purely cutaneous type (Jacobi), (2) the congenital, neviform type (Zinsser) and (3) the type in which the poikiloderma is the end result of other, earlier cutaneous diseases, e. g. lupus erythematosus, melanoderma, lymphosarcoma, mycosis fungoides, leukemia cutis or arsphenamine dermatitis. While our cases, as we have said, show striking similarities both clinically and histologically to Jacobi's original case, etiologically they undoubtedly are of the third type mentioned by Oppenheim, since the changes seem definitely to be the end result of a postarsphenamine dermatitis.

18. Montgomery, Hamilton, and O'Leary, P. A.: Poikiloderma atrophicans vasculare (Jacobi)? Arch. Dermat. & Syph. 25: 942 (May) 1932.

19. Ehrmann, in discussion on Jacobi's case: Verhandl. d. deutsch. dermat. Gesellsch., IX. Kongress 9: 321, 1907.

20. Oppenheim, Moriz, in Jadassohn, Josef: Handb. der Haut- u. Geschlechtskrankheiten, Berlin, Julius Springer, 1931, vol. 8, pt. 2, p. 635.

The question then arises: What is poikiloderma? From a review of the literature and from observation of our 2 cases of postarsenical poikiloderma-like changes it seems clear that there is in reality only one true type of poikiloderma, that originally described by Jacobi, the other types being merely variations of it, namely either the congenital, neviform type described by Zinsser or poikiloderma-like changes found in some other cutaneous disease either at the time the original disease is first observed or at some subsequent period during its course. One wonders whether if Jacobi had examined his patient for arsenic or if he had followed him over a long period he too might not have been able to classify the condition as being due to a postarsphenamine dermatitis, to a disease of the lymphoblastoma group or to some other disease in which poikiloderma-like changes occur as the result of a preceding dermatosis. On the basis of present knowledge of poikiloderma, meager though it is, one must assume that it is a symptom rather than a clinical entity, for while the term poikiloderma atrophicans vasculare is a valid descriptive one it gives no characteristic etiologic or pathologic picture to aid one in diagnosing the condition. In the last analysis we can say only that poikiloderma is a clinical descriptive term applied to a condition the main features of which are redness, telangiectasia, pigmentation and atrophy and which may be due to any one of a variety of causes.

SUMMARY

In 2 cases a postarsphenamine dermatitis ended in erythema, pigmentation, atrophy, telangiectasia and alopecia. The cutaneous symptoms presented by the patients were practically identical with those first described and named poikiloderma atrophicans vasculare by Jacobi.

CONCLUSIONS

1. Arsphenamine alone or a combination of arsphenamine and toxic factors is capable of causing poikiloderma or poikiloderma-like changes in the skin which are similar, both clinically and histologically, to Jacobi's poikiloderma atrophicans vasculare.

2. These poikiloderma-like changes result in permanent damage to the skin, the condition sometimes improving but never being completely cured.

One Hundred and Sixty-Eighth Street and Broadway.

ABSTRACT OF DISCUSSION

DR. CLYDE L. CUMMER, Cleveland: The authors' recounting of 4 cases of poikiloderma-like changes in the skin supplemented by the report of 2 observed by them establishes two points: first, that such changes may follow severe arsenical dermatitis and, second, that in seeing poikiloderma one must have in mind the possibility of an arsenical background. I have seen no such cases in the clinic where my associates and I do give a great deal of arsenical treatment, although I have to add that we have seen even less arsphenamine dermatitis or arsenical dermatitis since mapharsen has been employed. However, all have seen arsenical alopecia, I think, and a certain amount of pigmentation following exfoliative dermatitis, but not with telangiectasia. The authors' cases appear to correspond clinically and histologically to Jacobi's original report. I would like to have Dr. Cannon go into more detail, if possible, about the vitamin therapy. In the first case, as I understood, vitamins were used, but the great improvement came with the removal of the fetus. In the second case apparently vitamins had been used without any other particular factor which could be credited, and in both instances there was considerable improvement in the clinical result. I am interested in that because the statement of Dr. Cannon and his co-authors did not tell what type of vitamin therapy had been used. Dr. Duffy, of Memorial Hospital in

New York, informed me that good results had been obtained by some of his confrères who had radiodermatitis of the fingers by using vitamin B, I think the complex, plus liver extract. I tried it on 1 patient with a severe radiodermatitis and was surprised to obtain distinct improvement, with lessening of the atrophy and apparently some clearing of the telangiectasia. I wonder whether or not Dr. Cannon and his co-workers could fit in the improvement with vitamins. As to their conclusions, I think we shall all be in accord.

DR. JOHN E. RAUSCHKOLB, Cleveland: According to Oppenheim's concept of the poikilodermas, they are etiologically one of three kinds: (a) local type as in Jacobi's original case, (b) congenital or nevoid type and (c) vasculotoxic type. In considering the vasculotoxic type under which this case report falls, three theories have evolved: First, according to Milian's view of biotropism, activating micro-organisms are present in the human host through the power possessed by potent drugs injected into the circulation, producing inflammation of these various foci of infections in the skin; second, it could be a manifestation of sensitivity or true allergy in and around the vascular loops of the skin in support of Sulzberger's theory, or, third, it can be true drug intoxication of the peripheral cutaneous circulation whose concept we know as Osborne's. In support of Osborne's work we know that the trivalent organic arsenicals locate perivascularly and produce inflammation and sclerosis of the vessels with resultant atrophy and the poikiloderma or variegated color changes along with telangiectasia so typical in postarsenical dermatitis. I am more or less in accord with the authors and with Dr. Cummer, that we have here in these 2 cases reported at least a clinical picture produced by the intravenous injection of trivalent organic arsenicals with poikiloderma-like changes. In Jacobi's original case and also in some 120 cases that have been reported since then, these atrophic cutaneous changes have been insidiously progressive with no relationship to arsenic. Perhaps the therapy that has been instituted in the authors' cases of high vitamin content diet and liver extract is the reason why they have been able to change an atrophic cutaneous pathologic condition to one of a normal picture. Probably this therapy may prove of value in the true Jacobi type of poikiloderma.

DR. MAURICE OPPENHEIM, Chicago: In my article on Atrophy of the Skin in the handbook published by Jadassohn I take the position that poikiloderma atrophicans vasculare Jacobi should not be considered any more a real clinical and histologic entity. One part of the cases of poikiloderma atrophicans vasculare Jacobi is dermatitis atrophicans progressiva. Another part, like the cases of Petges and Clezat on the neck, are partly lupus erythematosus or partly caused by local influences. The third group—and to this group belong the 2 referred cases—are secondary changes of the skin caused by other skin diseases as lichen planus or by medication. In the Viennese Dermatological Society I presented several cases, in which such local or general influences were the cause of a typical clinical and histologic picture of poikiloderma atrophicans vasculare Jacobi. Therefore I believe that we must not complicate our science by introducing new clinical pictures. If one studies the dermatitis atrophicans group, as dermatitis atrophicans cutis idiopathica progressiva, one learns that Jacobi reported in 1906 a case of the later stages of dermatitis atrophicans progressiva. In this stage one finds the telangiectasias and follicular keratosis, and histologically the degeneration of the elastic and connective tissue fibers is present as is seen in the wonderful histologic slides of Dr. Cannon and his collaborators. If one looks over one's cases of poikiloderma atrophicans vasculare Jacobi, one will observe that the poikiloderma atrophicans vasculare is not a new clinical entity as Jacobi meant.

DR. A. BENSON CANNON, New York: Dr. Oppenheim was my teacher for a brief time many years ago; I am happy to see that he has much the same idea with regard to this condition that I have tried to emphasize here. Dr. Cummer spoke of the vitamin therapy that was given to these patients. Undoubtedly it was the liver extract and the vitamin B, given both hypodermically and by mouth, that was responsible for the increased general health and well-being that resulted. Whether the improvement in the appearance of the cutaneous symptoms was due also to the medication received is rather difficult to

say. Of course, the most pronounced change took place in the woman patient, after the removal of a petrified fetus. She gained 10 pounds within a few weeks and felt and looked much better. I have an idea that if one cushions atrophic skin with an excessive amount of fat one will automatically have mechanical improvement in appearance, even though the histologic atrophy will still be present. Unfortunately the pictures shown here were not taken until about three and one-half years after the patients had their initial dermatitis. One can, I believe, say pretty definitely, though, that the skin still shows the same degree of atrophy, and the scalp the same amount of alopecia, as existed in the beginning. It is almost inconceivable that there will ever be a complete return to normality in these respects, no matter what we may do by way of treatment. We are forced to believe that, although there has been a decided improvement in the appearance and general health of both patients, the underlying histologic changes must be regarded as permanent. Five years have passed, and the woman patient still has to wear a wig and will probably always have to do so, while the atrophic areas in the skin of both patients are no less atrophic, nor are they likely to become so.

TREATMENT OF GONORRHEA AT FITZSIMONS GENERAL HOSPITAL

A STUDY OF CASES FROM SEPT. 1, 1938
TO OCT. 31, 1940

DONALD B. PETERSON, M.D.
Captain, Medical Corps, United States Army
AND

EUGENE S. BEUCHAT, M.D.
Captain, Medical Corps, United States Army
DENVER

Our purpose in presenting this study of the results of treatment in 178 consecutive cases of gonorrhea treated during a period of twenty-six months is to report the results of newer methods of treatment and to set forth certain impressions gained from our experience on which a practicable treatment regimen can be based.

At Fitzsimons General Hospital from November 1935 to Nov. 1, 1940 the treatment of gonorrhea has been a responsibility of the Fever Therapy Department, and one of us (D. B. P.) has been in charge of this department since Sept. 1, 1938. During the period covered by this study the type of treatment has been changed from almost entirely fever therapy to almost entirely chemotherapy. Although the latter means of therapy has been carried out in another ward, all examinations of urethral and prostatic smears have been done in the Fever Therapy Department and the actual individual treatment of each patient has been dependent on the appearance of these smears.

Although all types of gonorrhea are included in this series, this report deals only with the results of treatment in the genitourinary infection.

The stain used is a modified Gram's stain, modified in that the smear is overstained with safranin, and decolorization is the final step in the process. This modification of the original Gram method of staining as used by the Fever Therapy Department, Fitzsimons General Hospital, is given in detail because adherence to this detail results in a clear, sharply stained smear,

of which the bacteria show the Gram characteristic, and the cellular elements show certain typical staining characteristics to be described later.

MODIFIED GRAM'S STAIN

Reagents:

1. Crystal violet, saturated alcoholic solution, 1 part; ammonium oxalate, 1 per cent aqueous solution, 4 parts.
2. Gram's iodine-potassium iodide: iodine 1 Gm., potassium iodide 2 Gm., distilled water 300 cc.
3. Counterstain: safranin, 1 per cent aqueous solution.
4. Decolorizer: 20 per cent acetone in 95 per cent alcohol.

Technic:

1. Apply crystal violet for one and one-half minutes, wash, blot and dry.
2. Treat with Gram's iodine for one and one-half minutes, wash, blot and dry.
3. Apply counterstain for three to four minutes, wash, blot and dry.
4. Decolorize with acetone-alcohol until no further traces of violet can be detected in the decolorizer, wash and dry.

Smears stained in this manner are shifted to the blue side so that the nuclei and cytoplasm of the pus cells are differentially stained.

All the patients who were the subjects of this report had urethral or prostatic smears containing gram-negative diplococci morphologically identical with gonococci, and "cures" reported relate only to this type of infection and not, for example, to the cure of any complicating arthritic process.

Since certain cases are said to be cured, a definition of the word "cured" is necessary. To be considered cured, of course the patient must be symptom free. The other essential is that the doctor must be convinced that the patient is cured. This conviction is based on examination of the urethral or prostatic smears microscopically. After three consecutive smears which show satisfactory improvement and are negative for gonococci are obtained, a sound is passed and 0.5 per cent silver nitrate is instilled. If, after this, three consecutive satisfactory smears are obtained, the patient is regarded as cured. Whether or not a certain smear is satisfactory is the crux of the whole situation.

Examination of the smears is done by the doctor himself, and, on the appearance of the smear, further treatment, change in treatment, discontinuance of treatment, as well as delay for further smear examination is determined. Here it must be stated that this delay is very important, because, although no gonococci can be found, it is frequently obvious to the examiner that the patient still has an active gonorrheal process. As will be noted in the accompanying photomicrographs, which were taken with a Wratten 25 filter over the light source, with healing there are very definite changes in the character of the cellular elements of the smear. The changes noted in healing are quantitative, qualitative and in color. Quantitatively the pus cells grow fewer and the gonococci disappear. Qualitatively the pus cells may become fragmented (especially after fever therapy) or may become more distinctly demarcated with pyknotic nuclei, later to undergo karyolysis. The general change in color of the pus cells is from entirely red cytoplasm and nuclei in the fresh ease to very dark pyknotic nuclei with pale pink or lavender cytoplasm in the healing ease. The changes described are the microscopic characteristics of cell necrosis. Karyorrhexis is seen especially after fever therapy, while after successful chemotherapy the slower changes of cell necrosis as typified by pyknosis and karyolysis and a

From the Medical Service, Fitzsimons General Hospital.

All photomicrographs were made on Eastman Spectroscopic Series S Type II plates with Wratten 25 filter on light source.

Members of the Laboratory Service, Fitzsimons General Hospital, made the photomicrographs and checked the staining technic described. The careful records of cases by the Medical Officers have made this report possible.

shift toward the blue staining side are characteristic. The implication of these changes is clear. If it can be assumed that the cellular exudate is in direct response to the presence of living gonococci and then if day by day that cellular exudate shows progressive cellular necrosis with the addition of no new, fresh pus cells,

Fig. 1 (case 1).—Urethral smear positive for gonococci, Oct. 21, 1938; $\times 1,000$.

it is evident that the exciting cause of the exudate no longer exists. The therapy itself may accelerate this cellular necrosis but will not prevent the influx of new cells except by therapeutic effect on the gonococci. On the other hand if, as may be expected from chemotherapy, these same necrotic changes are seen in a great majority of the pus cells yet there are found even a few new, fresh pus cells, it is evident that the exciting cause of the exudate is still present, though diminished. On this concept our criteria of cure and our indications for therapy rest. Our method of staining causes the characteristics of cell necrosis to become apparent, and the danger of overdecolorization is minimized. To the experienced examiner the appearance of the smear is indicative of the state of the patient's gonorrhea, and treatment is ordered accordingly. Certain patients have been kept in the hospital for many days and even weeks after the minimum number of smears have been negative for gonococci but have not been satisfactory otherwise, almost invariably to substantiate the examiner's belief that the patient was not cured. It is regrettable that the patients we regarded as cured were not checked by cultural methods. Thus it is that only 3 patients have been returned with further gonorrhea, each of these giving symptoms of acute new gonorrhea, history of exposure without prophylaxis, and symptom free periods for over six months. One of these was followed by monthly smear examination in fever therapy. Rightly or wrongly we believed these to be new infections.

Adequate treatment with the various agents to be described consists of:

- (a) Sulfanilamide: Eight Gm. a day for three days; 4 Gm. a day for five days.
- (b) Sulfapyridine: Thirteen Gm. the first day, then 1.5 Gm. a day for eight days.

(c) Fever Therapy: Nine hours of fever therapy at a rectal temperature of 106.8-107 F. given in such fashion that if more than one treatment is employed such treatments are not more than four days apart.

Such treatments with sulfanilamide and sulfapyridine as described may be considered as our routine, but in the last year, if the patient on an adequate sulfanilamide regimen did not show what was considered to be an adequate response in his smears by the fourth day, despite marked symptomatic improvement, he was immediately treated with sulfapyridine. In considering this amount of fever therapy adequate, we realize that for each case there is an amount of fever that will cure the gonorrhea, and it is only to have some point of departure that the amount stated is selected. Actually the minimum should be ten hours; if divided into treatments, they should be no further apart than on alternate days. If given further apart than this, we believe that the hours of fever cannot be regarded as cumulative therapeutically, and if given on succeeding days that the hours may be regarded as absolutely cumulative. If this belief is true, it explains why patients who have been given over fifty hours of fever therapy in weekly doses of about five or more hours remain positive for gonococci, whereas in these same patients two five hour treatments on successive days result in immediate cure.

RESULTS OF TREATMENT

A. *Sulfanilamide*.—1. Twenty-four patients were treated with sulfanilamide initially, received an average of 41 Gm. of the drug over an average of nine and four-tenths days and averaged twenty-seven and eight-tenths days from admission to clearance by fever therapy.

Fig. 2 (case 1).—One day after fever therapy, Nov. 4, 1938; $\times 1,000$.

2. Three patients, 2 after sulfapyridine reaction, 1 after fever therapy reaction, were given an average of 36.6 Gm. of sulfanilamide and averaged thirty-three and one-third days from admission to clearance.

3. Nineteen patients were treated with sulfanilamide initially, received an average of 39.1 Gm. of the drug over an average period of eight and four-tenths days, were also given urethral irrigations, and averaged fifty-

three and eight-tenths days to clearance. Most of these patients were given irrigations because the response to sulfanilamide therapy was inadequate.

4. Forty-eight patients treated initially with sulfanilamide averaged 200 Gm. of the drug, were sulfanilamide failures, and were treated by other means.

Fig. 3 (case 2).—One day after patient was started on a course of sulfanilamide, Oct. 14, 1938; \times 1,000.

Roughly 50 per cent of the patients treated by sulfanilamide initially can be considered to be cured by this drug.

B. *Sulfapyridine*.—1. Thirty-eight patients were treated with sulfapyridine initially, received an average of 24.5 Gm. of the drug over an average period of eight and seven-tenths days and were given clearance in an average of thirty and one-tenth days from admission.

2. Three patients had gross hematuria and renal colic after initial treatment with sulfapyridine with 10, 10 and 17 Gm. of the drug respectively and were treated by other means.

3. Twenty-four patients who had failed to show favorable response to, or to be cured by, adequate sulfanilamide therapy were given an average of 22.3 Gm. of sulfapyridine over an average period of seven and one-tenth days and were given clearance in an average of forty and eight-tenths days from admission.

4. Thirteen patients who had failed to be cured on adequate sulfanilamide therapy were given an average of 47 Gm. of sulfapyridine, failed to be cured by this drug and were treated by other means.

All of the 38 patients treated initially with sulfapyridine were cured by this drug.

C. *Fever Therapy*.—1. Forty-four patients received an average of one and eight-tenths fever treatments, with an average total of ten and seven-tenths hours at 106.8 to 107 F. and were cured of their gonorrhea.

2. Three patients received an average of two treatments with an average total of eleven and four-tenths hours and were not cured by this treatment. All three refused further fever therapy.

3. Fever therapy of 34 patients was attempted, but an adequate amount of fever could not be given because

of complications. Almost all of these patients had had previous unsuccessful sulfanilamide therapy.

D. *Additional Treatment*.—Twenty-three patients, of whom 12 had received adequate sulfanilamide therapy and 11 of whom had received both sulfanilamide and sulfapyridine therapy, were given such general treatment measures as irrigations, intravenous hydrochloric acid and the like and finally recovered after long hospitalization.

E. *Failures*.—Of the 178 patients treated, 3 were not cured of their gonorrhea.

The complications of treatment from sulfanilamide have been mainly febrile reactions, except for one severe case of agranulocytic angina and one bilateral sciatic neuritis. With sulfapyridine, 3 cases of gross hematuria with renal colic occurred. The complications of fever therapy occurring in those who have had sulfanilamide are at least five times as frequent and much more dangerous to life than in those who have not had sulfanilamide. The administration of oxygen is of great worth in these cases and in the event of complication is life saving. The chief complication is cerebral edema, which is thought due to anoxia of the brain tissue, which is in turn thought due to decreased oxygen carrying capacity of the blood. The altitude in Denver is no help, and when, as often occurs, the patient has been transferred to this hospital from a much lower altitude, the difficulties of administering fever therapy with safety are enormous. There were no deaths from complications.

ILLUSTRATIVE CASES

CASE 1.—Six and one-half hours of fever therapy were given on Nov. 3, 1938. The fever was terminated at that amount because of impending cerebral edema. As is our practice when a good start has been made on fever, the patient was prepared for another session the next morning, but a smear was taken just before his being placed in the Kettering hypertherm. Since he showed the good response illustrated in figure 2, this second session of course was not given. Finally,

the only cellular elements to be found were a few scattered epithelial cells. Most of the cells were necrosed by karyolysis, but in figure 2 karyorrhexis is evident.

CASE 2.—This illustrates an ideal response to sulfanilamide medication initially. In figure 3 is seen a very satisfactory smear response even though it is loaded with gonococci. The pus cells show a fragmenting, and no fresh cells are seen. Sulfanilamide

Fig. 4 (case 2).—Nine days after initial dose of sulfanilamide, Oct. 21, 1938; \times 1,000.

was started on Oct. 13, 1938. With the appearance of the smear in figure 3 one can be almost certain that this patient will be cured by sulfanilamide alone, and this excellent result, as seen in figure 4, is as expected.

CASE 3.—Repeated courses of sulfanilamide were administered, with a total in excess of 135 Gm. The prostatic smears were unsatisfactory; a small amount of fresh new pus cells occurring in clumps was continually in evidence. Figure 5 represents one of two such clumps found on the January 24 smear. Careful scrutiny of the January 24 smear revealed

one diplococcus, which was hardly diagnostic. Factually this diplococcus was interesting only, because it was otherwise evident that the patient required other treatment. After several abortive attempts at fever therapy which were abruptly and dramatically terminated by the cerebral edema which so often occurs in those who have had sulfanilamide, one ten hour

Fig. 5 (case 3)—Prostatic smear, Jan. 24, 1939. Note diplococcus, $\times 1,000$.

fever treatment was administered on Feb. 7, 1939. The response to fever therapy, as shown in figure 6, indicates that our belief that the patient was not cured by sulfanilamide was justified. Figure 6 is a low power photomicrograph of a smear that is made very thick to show the almost complete absence of cellular elements in the smear.

Fig. 6 (case 3).—Nine days after fever therapy, $\times 100$.

COMMENT

From studying and treating these 178 patients with gonorrhea we have gained certain impressions:

1. With sulfanilamide, about half the patients will show an immediate adequate response and will be cured. The other half will show an inadequate response,

although there will be great clinical improvement, and these patients should be treated by other means.

2. With sulfapyridine it appears that the immediate adequate response is greater than with sulfanilamide. Sulfapyridine therapy in sulfanilamide resistant cases is very efficacious. In gonorrheal epididymitis and arthritis the response to sulfapyridine therapy is much better than to sulfanilamide.

3. Fever therapy is the most efficacious treatment for gonorrhea but has definite disadvantages in that the treatment is expensive and of danger to the patient. The danger is increased by the previous medication with sulfanilamide, especially since now almost all patients have been so treated before they reach a hospital where fever therapy is available. Fever is of course the standard of good treatment in gonorrheal arthritis. We have had as good therapeutic results with fever therapy by giving eight and a half hours of fever to patients with chronic gonorrhea as with giving ten hours of fever to patients with acute gonorrhea. It has been our habit to give our fever patients a one hour trial treatment. In most cases this has been done on the day before the ten hour treatment, so that a total of eleven hours actually has been given. It is our experience, and thought to be important therapeutically, that if fever therapy for gonorrhea is given in more than one session these sessions should be no further apart than on alternate days.

4. Patients who do not show an adequate response to initial sulfanilamide therapy by the fourth day should be given either fever therapy or sulfapyridine because their chance of attaining a cure from sulfanilamide is not good, hospitalization is increased and the adverse effects of long continued sulfanilamide administration are courted without, in our opinion, therapeutic justification.

5. Estimating the progress of the case to determine effects of therapy, necessity for change in therapy and the time when cure is effected can practicably be accomplished by evaluation of the smear if the doctor in charge of treatment for gonorrhea (a) is in control of the staining of urethral and prostatic smears, (b) familiarizes himself with the microscopic appearance of necrosing pus cells and (c) examines the smears himself. A report of "negative for gonococci" from a laboratory, whether by smear or by culture, means nothing as far as aiding in treatment is concerned. But very specific inferences as to the state of the gonorrheal infection may be drawn from estimating the degree of necrosis in the pus cells of the smear and ascertaining whether or not fresh pus cells are present.

SUMMARY AND CONCLUSIONS

1. One hundred and seventy-eight consecutive patients were treated over a period of twenty-six months by adaptation of a routine treatment to the individual.

2. The criteria of cure presented are not considered to be absolute, not in the class of cultural methods for example, but are criteria which are entirely practicable and have proved to be successful.

3. The increased use of sulfanilamide and sulfapyridine therapy renders fever therapy more difficult to administer and more dangerous to the patient, but to a great extent sulfapyridine has supplanted fever therapy.

4. The method of smear examination and evaluation adopted forms the basis of a practicable therapeutic regimen.

TWENTY MINUTE CARDIAC ARREST
WITH COMPLETE RECOVERY

PRINCIPLES OF PREVENTION AND TREATMENT

HERBERT D. ADAMS, M.D.

AND

LEO V. HAND, M.D.

BOSTON

Every surgical team will at times be called on to face the serious responsibility of sudden cardiac arrest in the operating room. Such a catastrophe may develop at any point in the procedure—during preliminary preparation, during induction of anesthesia, during the operation or during certain essential postoperative procedures.

The exact physiologic mechanisms involved may be extremely difficult to analyze either at the time or later, after deliberate and full consideration. Prompt, adequate and properly selected methods of stimulating the return of cardiac function, maintaining adequate cerebral oxygenation, are essential in order to save the lives of these patients. However, the exact choice of these procedures and the possibility of their application under the existing circumstances are often difficult. As a result, routine measures and cardiants are applied, frequently without success. Primarily because of this uncertainty in management and results, we have been prompted to report the following case and its discussion, because it represents certain unusual aspects of this problem and has changed some of our fundamental concepts regarding cardiac resuscitation.

REPORT OF CASE

A man aged 20 was first seen at the Lahey Clinic on July 1, 1941 with a history of chronic cough and hemoptysis of four years' duration. Complete studies showed a bronchiectasis of the left lower lobe and spontaneous pneumothorax on this side. Otherwise his examination was essentially negative.

The patient was admitted to the New England Deaconess Hospital on Sept. 26, 1941 for lobectomy. On the fifth day he was prepared for operation. Preoperative blood pressure was 124 mm. systolic and 60 mm. diastolic, the pulse rate 88, the respiratory rate 24. Premedication consisted of $\frac{1}{8}$ grain (0.01 Gm.) of morphine, $\frac{1}{150}$ grain (0.0004 Gm.) of scopolamine subcutaneously and $1\frac{1}{2}$ grains (0.1 Gm.) of pentobarbital sodium by mouth, given at 12:30 p. m.

At 1:20 a 10 mm. flexible metal endotracheal catheter with balloon cuff was introduced into the trachea under direct vision after topical anesthesia with 10 per cent cocaine hydrochloride. General anesthesia was started at 1:23. The anesthetic mixture for induction was approximately 30 per cent cyclopropane and 70 per cent oxygen in a closed circuit with carbon dioxide absorption. The blood pressure rose to 160 mm. systolic and 100 mm. diastolic; the pulse rate was 72 and the respiratory rate 22. After induction, the balloon cuff was inflated to insure a closed system. The endotracheal tube was connected to the conduits of the gas machine by means of adapters. Anesthesia was then maintained by a mixture of approximately 20 per cent cyclopropane in oxygen.

The operation was started at 1:55 and the thoracic cavity opened at 2:17. At this point the blood pressure was 140 mm. systolic and 96 mm. diastolic, the pulse rate was 104 and the respirations were very shallow and rapid. Periods of passive positive respiration of one to two minutes were resorted to at five minute intervals in order to insure an adequate oxygen-carbon dioxide exchange. The blood pressure and pulse continued at about the same level and were never lower than the preoperative level. At 3:15 the bronchus and vessels leading to the left lower lobe were ligated, the specimen was removed and the stump was sutured and inspected. At 3:25 p. m., two

hours after the start of anesthesia, it was decided to aspirate a small quantity of secretion in the trachea through the endotracheal tube. At this time the blood pressure was 140 mm. systolic and 100 mm. diastolic, and the pulse rate was 108. The operative procedures were halted during this interval to permit aspiration, and the surgical team, watching the upper lung and heart, was prepared to prevent possible trauma to the remaining lung tissue if the patient should suddenly cough or strain. After the apparatus for anesthesia was disconnected at the mouth and a number 14 French catheter was introduced through the endotracheal tube for suction, the patient gave three convulsive coughs. At this point the surgeon remarked that the heart had ceased beating and was semidilated and tense. Rhythmic cardiac compression simulating systole was instituted immediately and the patient was put in 5 degree Trendelenburg position. At 3:28, three minutes after cessation, 2 minims (0.12 cc.) of neosynephrin hydrochloride was injected into the musculature of the ventricle; at 3:29 an additional 2 minims of neosynephrin hydrochloride was given into the ventricle and artificial systole was continued. At 3:30, five minutes after cessation, 10 minims (0.6 cc.) of 1:1,000 epinephrine hydrochloride solution was injected, half into muscle and half into the ventricular cavity. The heart began to show fibrillatory movements and then gradually to beat vigorously for five to six beats. It again relapsed into fibrillation and then stopped. A second dose of 1 cc. of epinephrine was introduced, without effect. Actual cardiac compression simulating systole was continued until twenty minutes later, when the heart again began spontaneous rhythmic contractions, at 3:45. At 3:48 p. m. 7 cc. of nikethamide was given into the vein of the foot.

At the instant of cessation of the heart beat all anesthetic gases were discontinued and artificial respiration (28 to 32 a minute) was begun and maintained by strong rhythmic pressure (12 to 16 mm. of mercury) on the rebreathing bag, with only oxygen flowing. At 3:40 p. m., fifteen minutes after cessation, 15 cc. of procaine hydrochloride was administered intramuscularly into the left shoulder. Throughout this procedure the patient was cyanotic and the color of his head and shoulders was violescent, but he did not have the grayish, waxy appearance of death. Within a few seconds after the heart resumed spontaneous rhythmic contractions (3:45 p. m.) spontaneous respiratory excursions progressed from rapid shallow respirations to rapid (36 a minute) exaggerated respirations. At 3:50, or twenty-five minutes after cessation of the heart, the patient's color became a livid pink. The blood pressure was first obtained at this time; it measured 160 mm. systolic and 120 mm. diastolic, and the pulse rate was 118. Respirations gradually quieted as to excursion and rate. For the remainder of the operation only oxygen was administered.

Closure of the chest was accomplished in the ordinary manner, and the operation was concluded at 4:50 p. m., one hour and twenty-five minutes after initial cardiac cessation. The operative time was three hours. At this time the blood pressure was 114 mm. systolic and 64 mm. diastolic; the pulse rate was 124. The patient was returned to a private room at 5:10, after he responded to spoken commands, and with the second of two 500 cc. transfusions running. He was placed in an oxygen tent immediately, and the bed was placed in shock position.

Preoperatively a continuous intravenous drip had been started through a gold cannula to the right long saphenous vein at the ankle, and during operation the patient received two transfusions of 500 cc. each. Immediately after operation it was noted that there was no pulse in the right radial artery, but after one hour the pulse in the right arm had returned to its normal magnitude. The operative position, with the right arm dependent, possibly was a factor in the production of this prolonged arterial spasm.

SUMMARY OF POSTOPERATIVE CONVALESCENCE

The patient's immediate postoperative recovery was entirely satisfactory and differed but little from the average lobectomy case. He was mentally clear and alert, and there were no signs of cerebral damage demonstrable at any time. The upper lobe was well aerated and expanded from the beginning, but, because he had a low grade fever, closed drainage was maintained for two weeks and simply converted into open drainage through

From the Department of Surgery (Dr. Adams) and the Department of Anesthesia (Dr. Hand), the Lahey Clinic.

the same tube at the end of the second week. His low grade fever gradually subsided and, since his condition was good, he was allowed to be up on his seventeenth day. On his second day up he complained of persistent frontal headache and his temperature rose to 103 F. He was put back to bed and a course of sulfathiazole was started. Our immediate consideration was the possibility of brain damage and brain abscess. He was seen by the neurosurgical department, which found no abnormal neurologic signs and a lumbar puncture was negative in every respect. Preoperatively he was known to have a chronic pansinusitis, and this was reviewed by our nose and throat consultant and did not seem to be the source of his systemic reaction. He continued to have high temperature, his headache subsided after a few days and he complained of no symptoms whatever thereafter. The continued chemotherapy had no effect on this temperature. Roentgenograms of his chest showed a well expanded upper lobe and no demonstrable pleural infection. Repeated thoracentesis produced no pus. However, because of his continued fever a rib resection was done, establishing more adequate drainage and removing a small amount of fibrin lying along the posterior gutter. This did not affect his temperature, which continued swinging for several more weeks and gradually subsided. During all this time he had no symptoms and felt well. During his convalescence he had two electrocardiograms which were entirely normal, and before discharge from the hospital an electroencephalogram was also made, which was normal. He left the hospital in good condition sixty days after operation.

COMMENT

Discussion of this case may be subdivided into three physiologic divisions. First, what were the etiologic factors causing this cessation? Second, what was the rationale of the treatment employed in this case? Third, what preparation and regimen of treatment might be of value (1) to prevent or (2) to treat a similar condition more adequately if it should arise in the future?

Etiology.—Etiologic factors which might cause this sudden cardiac arrest are (1) idiosyncrasy to the anesthetic drug, (2) onset of ventricular fibrillation, (3) occurrence of a vagovagal reflex resulting in cardiac arrest. Idiosyncrasy to the agent, while possible, is not probable in view of the time of occurrence; that is, two hours after the start of its administration. The onset of ventricular fibrillation can be ruled out, as the surgical team was watching the exposed heart and did not note any fibrillatory movement when massage was started.

In this instance cessation was most likely the result of a vagovagal reflex influenced by the following factors and facts: With the wearing off or loss of topical anesthesia (cocaine) after two hours of operating, vagal irritability returned to this region. Also an increase in the excitability of the vagus fibers resulted from the depression of the cells of the medullary center. The factors influencing this depression were medication, anesthesia and suboxygenation resulting from surgical diminution of vital capacity, as evidenced by the shallow respirations. Stimulation of the vagovagal reflex resulting in cardiac arrest was initiated when the suction catheter irritated or stimulated the irritable tracheal bifurcation, as evidenced by the cough spasm noted just prior to cardiac cessation. Although this reflex may have been transitory, the effect, inhibition or cessation, persisted.

A summation of physiologic factors which may be applicable to this case is found in the chapter on "Physiology of the Heart," of Starling's "Human Physiology."¹ These factors are (a) the increase in excitability of the vagus, (b) the site of vagal action on the heart, (c) vagal mode of action and drugs influencing it and (d) the effect of narcosis and anes-

thesia on vagal action. These factors are more or less explained in the following quotations from "Human Physiology":

A. It is remarkable that the excitability of the vagus fibers is dependent on the condition of the cells of the medullary centers. Thus, if the centers are depressed by narcotics, the vagus fibers become more excitable.

B. The action of the vagus fibers on the heart is almost identical in frog and mammal and is exerted primarily on the auricle. . . . Generally, the vagus absolutely stops the action of all parts of the auricles; in such cases the ventricles also cease beating.

C. Many facts point to the inhibitory impulses acting on the heart muscle itself. . . . These nerve effects are paralyzed by atropine, after administration of which no inhibitory effects can be produced by stimulation of nerve or muscle on any part of the heart. . . . Although various views as to the nature of inhibition have been put forward from time to time, the present tendency is to ascribe both the excitatory and the inhibitory effects of all nervous stimulation to the liberation, at the nerve ending, of small amounts of highly active substances, which are quickly destroyed in the tissues. According to Loewi, the vagus acts by producing some chemical substance which has the power of depressing the activity of the different parts of the heart. . . . It is now generally accepted that this substance is acetyl choline. . . . The action of acetyl choline is antagonized by atropine.

D. When the arterial system is dilated, so that the mean systemic pressure during cardiac inhibition is low, or when the asphyxial gasps of the animal are prevented by anesthesia or by a section of the spinal cord, the heart may fail to recover from the inhibition produced even by transitory stimulation of the vagus. In such cases it is necessary to knead the heart in order to restore its rhythmic action.

Rationale of Treatment in This Case.—The rationale of treatment in this instance was governed more by urgency and expediency than by any prepared plan or organized regimen for treatment.

Artificial systole to maintain circulation was immediately started by the surgeon. The patient was placed in 5 degree Trendelenburg position to facilitate cerebral circulation. Neosynephrin, a synthetic product, was used initially as the pressor stimulant because cyclopropane was the anesthetic agent. Laboratory and clinical reports² have demonstrated an increase in irritability of cardiac muscle, with a tendency to ventricular fibrillation when epinephrine is employed as a pressor substance in the presence of tissue saturation with cyclopropane. Procaine was given, with the hope of neutralizing this sensitization.³ When no effect was obtained from the second injection of neosynephrin, epinephrine then was used. Although this first injection of epinephrine initiated spontaneous cardiac activity, this action rapidly progressed to the undesirable state of ventricular fibrillation to cessation. A second dose of 1 cc. of epinephrine had no effect. Artificial systole was reestablished during fibrillation and subsequent cessation. The heart resumed spontaneous rhythm twenty minutes after the initial cessation. The stimulus undoubtedly was the rhythmic compression of the heart during artificial systole.

Simultaneously, artificial respiration was continued throughout this twenty minute period to maintain adequate pulmonary ventilation. In the absence of mechanical apparatus as recommended by Crafoord,⁴

Mautz⁵ and Beck,⁶ the anesthetist immediately started and maintained artificial respiration (28 to 32 per minute) by rhythmic pressure (12 to 16 mm. of mercury) on the rebreathing bag of the gas machine. The anesthetic mixture was immediately replaced by oxygen in the breathing circuit. Oxygen under pressure was supplied to the pulmonary tree by this system of endotracheal tube with inflated cuff, adapter and gas machine. This method resulted in demonstrable, adequate expansion of the lung. The endotracheal tube insured a patent airway. This type of closed system of endotracheal tube with inflated cuff and adapter safeguards against simultaneous, undesirable inflation or acute dilatation of the stomach, which can readily occur when a mask is employed over the mouth and nostrils and strong positive pressure is used. Nikethamide was administered intravenously as a stimulant after the return of circulation and respiration because of its mildly cardiac and pronounced respiratory effect.

Artificial cardiac diastole was most likely produced by the following factors: 1. The inherent elasticity and muscle recoil facilitated auricular and ventricular filling. 2. The intermittent changes in positive pressure exerted during artificial respiration resulted in differences in venous pressure both in the vena cava and in the pulmonary circulation. Exaggerated pulmonary ventilation facilitated blood flow to the auricle from the lungs. The definite discernible artificial diastole probably was dependent on these factors.

During this twenty minute interval, oxygenation was maintained by artificial respiration and circulation. Beck stresses the importance of oxygenation to prevent cellular damage and especially medullary cell damage, with respiratory death. The prevailing impression is that cortical cells begin showing cellular degeneration in the form of trydoidolysis five to seven minutes after being deprived of oxygen. Beck mentions animal experimentation by Weinberger,⁷ placing this time at three to five minutes. The lack of progressive signs of anoxia was the motivating influence in the continuation of manual oxygenation over the twenty minute period until circulation and respiration resumed normal activity.

RECOMMENDED METHODS OF PREVENTION AND TREATMENT

Obviously the best management of this problem is its prevention. This necessitates an attempt to avoid the onset of this inhibitory action of the vagus on the heart. This is accomplished first by prevention of increased vagal irritability resulting from suboxygenation or depressing effects of narcosis or anesthesia and second by the prevention of afferent reflexes, or vagovagal reflexes, providing the inhibitory efferent effect. The latter is accomplished by avoiding or blocking, whenever possible, stimuli affecting the afferent pathways of the vagal nerve. It is our opinion that necessary procedures, such as aspiration of trachea and hilar manipulations, which may produce afferent vagal stimulation, should not be carried out without adequate block of these pathways. Local infiltration of hilar plexes or topical application of anesthetic to the tracheo-bronchial tree should afford some protection. In addition,

the efferent effects of the vagus nerve are blocked directly at the myoneural junction by an adequate dose of atropine. Atropine $\frac{1}{15}$ grain (0.0008 Gm.) is considered by many to be an adequate dose. This can be given as part of the preoperative medication and repeated as indicated, depending on the duration of the operation.

However, when this catastrophe occurs, the following plan of treatment is recommended. Adequate tissue oxygenation by means of artificial circulation and pulmonary ventilation should be instituted immediately and simultaneously. This is accomplished by the following methods:

Artificial Respiration.—An endotracheal tube, preferably with a balloon cuff attachment, should be inserted to insure a patent airway. Inflation of the balloon cuff insures a closed system with the distribution of the positive pressure within the pulmonary tree only. In the absence of apparatus to produce intermittent positive pressure (Mautz), rhythmic pressure on the rebreathing bag of the closed circuit will insure adequate pulmonary ventilation. Carbon dioxide absorption is essential to prevent accumulation of this product within the closed system. Rhythmic pressure of 12 to 16 mm. of mercury at a rate of 28 to 32 per minute is recommended.

Artificial Circulation.—Circulation of the blood should be maintained by artificial systole in the form of rhythmic manual compression. It is advisable to synchronize this rhythm with that of artificial respiration to allow for the associated artificial diastole. This necessitates cardiac accessibility.

If the chest is open, the pericardium can be opened from either side and an efficient artificial systole instituted. If the abdomen is open, the approach may be made through the left diaphragm. If neither chest nor abdomen is open at the time, a rapid exposure of the heart can be accomplished by an intercostal incision in the anterolateral portion of the left chest, cutting the costal cartilage above and below. The influence of gravity on the cerebral circulation should be considered. A few degrees of Trendelenburg is a factor in aiding cerebral circulation.

Cardiants may be used in physiologic doses. Although their use is a standard method of treatment, many untoward and fatal effects have been observed. It is our opinion that the best treatment combines the outlined recommendations and the very judicious use of cardiants.

CONCLUSIONS

1. This case demonstrates that the time interval of cardiac arrest compatible with normal recovery is much longer than was formerly appreciated.
2. This recovery is dependent on adequate tissue oxygenation, especially of cerebral tissue.
3. This is accomplished by immediate and simultaneous artificial circulation and respiration.
4. Efficient artificial circulation is dependent on more than simple cardiac massage.
5. The measures instituted must approach as closely as possible the normal physiologic cardiorespiratory sequence.
6. Synchronized artificial respiration associated with artificial cardiac diastole followed by artificial cardiac systole more nearly approaches this normal sequence.
7. This case with complete recovery following prolonged cardiac arrest demonstrates the value of these principles of prevention and treatment.

Clinical Notes, Suggestions and New Instruments

LARYNGEAL STRIDOR ASSOCIATED WITH HYPOCALCEMIA IN AN ADULT

POSTOPERATIVE PARATHYROID DEFICIENCY WITH OTHER CONTRIBUTING ABNORMALITIES

BENJAMIN V. WHITE, M.D., HARTFORD, CONN.

Laryngeal spasm as a symptom of tetany in infancy is well recognized. In later life it is rarely encountered. Guild¹ states that it almost never occurs after the second year. The following report of laryngeal stridor associated with parathyroid tetany indicates that under certain circumstances the symptom does occur in adult life. A Jewish housewife aged 70 had a bilateral thyroidectomy performed for colloid goiter when she was 47. At 60 she had a bilateral iridectomy done for cataracts, at 63 she began to notice the onset of hoarseness, at 64 the initial phase of chronic congestive heart failure and at 69 acute attacks of laryngeal stridor. The Chvostek and Trousseau signs were positive, the serum calcium was found to be 4.2 mg per hundred cubic centimeters, and the attacks of stridor were instantly relieved by intravenous calcium gluconate. Control of the serum calcium level with dihydrotachysterol relieved the symptom.

Albright² reports that he now has under observation a similar case. In his case the laryngeal stridor also developed many years after thyroidectomy, at a time of physical disability and in association with a paralyzed vocal cord. His patient, however, has not responded so definitely to treatment with dihydrotachysterol.

REPORT OF CASE

History—G. S., Jewish housewife aged 70, was essentially well until she was 47 (1917), at which time a colloid adenoma of the thyroid was removed. The postoperative chart indicates an uneventful convalescence. Ten years later the onset of bilateral lenticular opacities was observed and three years subsequently, at the age of 60 (1930), iridectomies were performed. At 63 (1933) she first began to notice increasing hoarseness and one year later she commenced to suffer from prolonged periods of edema of the ankles. The edema was successfully treated by her private physician with digitalis, diuretics and rest. At 66 (1936) she noticed her first attacks of laryngeal spasm with inspiratory crowing respiration. These occurred at intervals of several weeks and were usually precipitated by emotional tension, particularly by anger. The attacks occurred with gradually increasing frequency until she was 69 (1940), at which time they became much more prolonged and occurred independently of emotional stress. She became cyanotic during the attacks. Six months before admission she became so weak that she could seldom go out, and increasing dyspnea and orthopnea developed. These symptoms and her stridulous breathing became worse until the time of admission.

Examination—On physical examination the patient was pale, senile and chronically ill and lay propped up in bed in constant mild dyspnea. Basic respiration was regular. At times, however, she was seized with sudden attacks of crowing inspiratory stridor which would last for from two to three minutes. In the more severe attacks deep cyanosis would develop, producing a clinical picture that was truly alarming. The skin was not remarkable. The eyes showed the scars of iridectomy. A scar of the thyroidectomy was present. There was moderate distention and pulsation of the veins of the neck. The heart was clinically enlarged. The heart sounds were regular, of a tick-tack quality, with a soft blowing apical systolic murmur. The blood pressure was 127 systolic and 68 diastolic. The radial arteries were palpable. There were coarse rales at the bases

of both lungs. The abdomen was distended with fullness in the flanks, shifting dullness and a fluid wave. There was pitting edema of the abdominal wall and of the lower extremities. Laryngoscopic examination revealed paralysis of the right vocal cord.

Repeated examinations of the urine revealed a specific gravity varying from 1.010 to 1.025, traces of albumin but no sugar. There were small numbers of white blood corpuscles and rare hyaline and fine granular casts in the sediment. On admission the hemoglobin content was 65 per cent (Hayden-Hausser), the red blood cell count 4,370,000 and the white blood cell count 9,250. The stained smear showed adequate platelets and moderate achromia. The differential count showed 89 per cent polymorphonuclears, 7 per cent lymphocytes and 4 per cent large mononuclear cells. The nonprotein nitrogen was 35 mg per hundred cubic centimeters, the total serum protein 8.4 Gm, serum phosphorus 4.3 mg and serum alkaline phosphatase activity 4.6 Bodansky units. Serum calcium determinations on three successive days were 4.2, 4.5 and 4.8 mg per hundred cubic

The abscissa illustrates the serum calcium level in milligrams per hundred cubic centimeters and the disappearance of laryngeal stridor, and at the bottom of the chart is given the dosage of dihydrotachysterol (A.T. 10). The ordinate represents time in hospital days. Note that following the administration of dihydrotachysterol the blood calcium level rapidly rose in association with continued relief of the laryngeal spasm.

centimeters. (The latter two readings followed calcium administration.) Stool examinations were negative for occult blood. A phenolsulfonphthalein renal function test showed 19 per cent excretion of dye at the end of one hour. Roentgen examination of the long bones, skull and spine showed moderate demineralization of the lumbar spine.

Hospital Course—Although the cardiac reserve was obviously very limited, there was considerable improvement in dyspnea and edema as the result of bed care, thoracenteses, diuretics and digitalization. This improvement did not, however, appear to influence the periods of inspiratory laryngeal stridor, which occurred many times a day, lasted for several minutes and at times were accompanied by an alarming degree of cyanosis. At the time of these attacks the Trousseau sign was definitely positive and the Chvostek sign slightly positive.

On the seventh hospital day 1 Gm of calcium gluconate was administered intravenously during a seizure, with immediate

2 Albright, Fuller. Personal communication to the author.

relief that persisted for about twenty hours (shown in the chart). In view of the instant response to intravenous injection, 3 Gm. of calcium gluconate and 1 cc. of percomorph oil were administered daily by mouth. This regimen was associated with a slight elevation of serum calcium (from 4.2 to 4.8 mg. per hundred cubic centimeters) and with partial alleviation of respiratory stridor. On the eleventh hospital day this regimen was supplemented with dihydrotachysterol, which was given in doses of 2 cc. daily for a period of eleven days and in doses of 1 cc. daily thereafter.

During the eleven day period in which 2 cc. of dihydrotachysterol was given, the serum calcium rose from approximately 5 mg. to approximately 7 mg. per hundred cubic centimeters, and the respiratory stridor disappeared entirely and permanently. During the first six days after reduction of the daily dose to 1 cc. the serum calcium continued to rise, attaining the level of 8.7 mg. per hundred cubic centimeters on the twenty-seventh hospital day.

After the twenty-seventh hospital day serum calcium determinations were discontinued, and the dosage of dihydrotachysterol was regulated by means of urinary calcium. This was crudely determined by means of the Sulkowitch test.³ Observations were made on the twenty-fourth, twenty-fifth, thirty-second and thirty-fourth hospital days, at which times a "moderate amount" of calcium was present. This indicates satisfactory dosage.

COMMENT

The serum calcium level of 4.2 mg. per hundred cubic centimeters is extremely low. If this degree of hypocalcemia had developed suddenly after the thyroidectomy at the age of 47, death would almost certainly have ensued, yet the postoperative course at that time appears to have been uneventful. One must conclude that the hypocalcemia developed gradually. The development of cataracts suggests that it was well established by the age of 57. The reason for this gradual development of hypocalcemia is not clear. Retention of phosphorus caused by severe renal failure is known to produce hypocalcemia in some instances.⁴ In this case there was impaired excretion of the dye but no evidence of retention of nitrogen or phosphorus. This explanation is therefore inapplicable. Hypoproteinemia is usually associated with a mild degree of hypocalcemia, but in this case the serum protein was normal. A third possible explanation is that one or more parathyroid glands were left in situ at the time of operation and subsequently atrophied. Such residual tissue or its vascular supply might well have become involved in an area of scar tissue and gradually strangulated. A less conventional hypothesis is that fatigue atrophy, such as the hydropic degeneration of islet tissue observed by Allen⁵ in partially pancreatectomized dogs, may have occurred. The production of such atrophy by continued administration of anterior pituitary extracts and its prevention by adequate insulin dosage have led Haist, Campbell and Best⁶ to certain observations on the possible prevention of diabetes mellitus.

No more clear is the reason why symptoms of laryngeal stridor should have made their appearance so late in life. The paralyzed vocal cord was undoubtedly present immediately after the thyroid operation, and there is evidence from the lenticular opacities that a certain degree of hypocalcemia also preceded the onset of stridor. Chronologically the onset of stridor was associated with the onset of chronic myocardial failure. All these factors are probably important, and their coincident occurrence probably explains the rather bizarre phenomenon of laryngeal stridor as a symptom of hypocalcemia in an adult.

SUMMARY

A woman with paroxysmal laryngeal stridor associated with hypocalcemia was treated with dihydrotachysterol. Elevation of the serum calcium level resulted in complete disappearance of the paroxysms. The symptoms developed long after the thyroid gland had been surgically removed. A paralyzed vocal cord and the gradual onset of chronic myocardial failure were complicating abnormalities which presumably played a role in the development of the syndrome, one which though common in infancy almost never occurs in adult life.

PYOURETER SEVENTEEN YEARS AFTER NEPHRECTOMY

SELVAN DAVISON, M.D., NEW YORK

The occurrence of pyoureter many years after nephrectomy without complete removal of the corresponding ureter is not common. In the case here presented the clinical picture caused by pyoureter was characterized mainly by obscure fever of six weeks' duration.

REPORT OF CASE

History.—R. W., a woman aged 53 born in Russia had had rheumatic fever in childhood. A right mastoidectomy was performed thirty years before the present admission. An appendectomy was done five years later, followed in two weeks by a right ureterolithotomy. Eight years later a right nephrectomy for calculus pyonephrosis was performed at another hospital. For many years, until four years ago, the patient had attacks of cramping pain in the right upper quadrant of the abdomen brought on by food and relieved instantly by licorice powders. Eight years before this admission she was told that she had gallstones but refused operation. During the last seventeen years, there were no genitourinary symptoms. Dysuria, hematuria, frequency, urgency and attacks of renal colic had been completely absent. The menopause occurred at the age of 49.

Six weeks before admission the patient was suddenly seized with sharp pain in the right lower quadrant of the abdomen and had a temperature of 102 to 103 F. for several days. She then was out of bed, although the pain persisted and numerous chilly sensations occurred. For six weeks she complained of moderate generalized malaise. The day before admission, the pain and chilly sensations increased noticeably, and the temperature was 102.5 F. The patient was then admitted to the hospital.

Examination.—The patient had a sallow complexion. She was not in acute distress. A loud systolic murmur was heard all over the precordium and was heard best at the pulmonic area. The second pulmonic sound was greater than the second aortic sound. The blood pressure was 120 systolic and 75 diastolic. There was well defined tenderness in the right lower quadrant of the abdomen and a sensation of fullness in the upper part of that area. On pelvic examination the right fornix was felt to be full and boggy, and there was a definite sensation of thickening and induration in the region of the right broad ligament. Rectal examination gave essentially negative results. The chest was clear. Icterus was not noted.

The urine on admission was essentially normal. After several days a few white blood cells were noted. The first urine culture showed *Streptococcus hemolyticus* alpha. Two weeks later a second urine culture revealed *Staphylococcus aureus* beta and diphtheroids. On two examinations no acid-fast bacilli were found in urines taken with the cystoscope. Blood culture on admission showed *Staphylococcus aureus* alpha in three flasks. The hemoglobin content was 83 per cent and the white blood count was 13,250 per cubic millimeter, of which 58 per cent were segmented polymorphonuclear cells and 2 per cent nonsegmented; there were 28 per cent lymphocytes and 12 per cent monocytes. The blood urea nitrogen

was 10 mm. per hundred cubic centimeters, the ieteric index was 6, the cholesterol was 190 mg., the blood Wassermann reaction was negative and blood agglutination tests for typhoid, infectious mononucleosis and undulant fever were negative.

Course.—After several days, because of a positive blood culture, the patient was given sulfathiazole, 1 Gm. every four hours. Chemotherapy was instituted at the time that the temperature was apparently falling spontaneously. The drug had to be discontinued after three days owing to the development of a classic although mild sulfathiazole eruption of the skin. The blood cultures remained sterile subsequent to the first positive report.

The mass in the right lower quadrant of the abdomen was suggested on admission to be due to an abscess in the stump of the right ureter which had not been removed following a nephrectomy seventeen years before. A barium enema was given to rule out the possibility of a neoplasm of the cecum. The barium enema gave negative results, except that three concretions, probably representing gallstones, were seen in the right upper quadrant of the abdomen. An intravenous pyelogram was then done and revealed a well visualized left upper urinary tract with enlargement of the left kidney. Distorted calices were noted, and these gave the appearance of multiple cysts. The left ureter was normal. The right upper urinary tract was not visualized, and the outline of the right kidney was not seen. An ovoid concretion 1.5 cm. in length was seen over the right wing of the sacrum. The relationship of this concretion to the ureter was not demonstrated, although it was reported as probably representing a ureteral calculus. There was a small concretion in the midline of the pelvis overlying the lower sacrum.

The patient's general condition continued to be surprisingly good. There was little spontaneous pain and the temperature ranged around 101 F. Cystoscopy was performed by Dr. Leo Edelman.

Cystoscopic Observations.—Two hundred and fifty cc. of turbid urine was evacuated from the bladder. A low grade cystitis was noted, with mucopus on the floor especially in the region of the right ureteral orifice. The left ureteral orifice was normal, and crystal clear urine was seen coming from the left ureter, into which a catheter was easily introduced. The operator was unable to engage a catheter on the right side and an orifice was not definitely visualized because of inflammation and edema. The margin of the inferior sphincter was slightly elevated and congested. The bladder urine showed frequent white blood cells. Ureteral urines were normal.

Sufficient evidence was now at hand to be certain that a periureteritis and a ureteral abscess were present. Therefore, exploratory laparotomy was performed by Dr. Leo Edelman. The distal remaining 8 inches (20 cm.) of the right ureter was revealed. Intense periureteral inflammation and thickening were present. The proximal portion of the ureteral stump contained a large abscess, and through the proximal opening purulent material was flowing. The distal end of the ureter contained a calculus which blocked the ureteral orifice. The entire remaining 8 inches of the right ureter was excised and a drain left in the operative site.

The postoperative course was slightly rough for four days, during which time there was fever to 105 F. She received sulfathiazole during these four days and the temperature came down sharply to 100 F. The remainder of the postoperative course was essentially uneventful, although moderately slow because of drainage from the wound. The drainage eventually ceased and the patient was discharged cured.

COMMENT

Jeck¹ has said that "given an infected ureter, the corresponding kidney of which has been removed, whether or not the stump will become a pus pocket, depends chiefly on two factors: (1) the presence of an obstruction, such as stone, stricture or

kink and (2) injury to the nerve supply of the ureter, either by operative trauma or peri-ureteritis and consequent scar formation."

The presence of a calculus in this case bears out the observation that obstruction is necessary for the formation of a pus pocket. No pathologic process remains in the great majority of cases of nephrectomy, although the ureter or part of it is left in situ. This is due to the fact that adequate drainage of the stump usually occurs. Latchem,² in his experimental work on the physiopathology of the ureter, has shown this to be so. His conclusions are: 1. Absorption of the contents of a distended ureter is very limited if it occurs at all. 2. If infection is present in the ureteral contents, it may spread through the ureteral wall and give rise to periureteral infection and abscess formation.

The most interesting fact in the case history is that the patient was symptom free for seventeen years following nephrectomy. Hennessey,³ in reviewing reports by Roedelius⁴ and Brongersma⁵ of pyoureter developing seventeen and twenty-three years respectively after nephrectomy, states that the reason was delay in recognition. He believes that the majority of such cases are and should be detected between a period of a few months and three years after nephrectomy. While this is probably true in the majority of cases, the patient here described was symptom free and did not seek a physician's advice for any genitourinary complaints for seventeen years. There was no dysuria and even when she was in the hospital there was no pyuria or hematuria. Consequently, one may postulate the possibility of sudden exacerbation of a latent infection by an unknown cause. Apparently sufficient ureteral contractions occurred⁶ to cause spillage of the contents, periureteritis and *Staphylococcus aureus* bacteremia. In the case just presented, the calculus was far down the ureter and blocked drainage into the bladder. The presence of some inflammation at the right ureteral orifice was probably a concomitant of the severe periureteritis. Since patency of the lower end of the ureter was blocked, infection sought another outlet. This was through the free end of the ureteral stump. One cannot tell when the actual formation of the periureteritis and the abscess took place. It may have been a slow, symptomless process for seventeen years which suddenly lit up. It is possible that for many years the calculus was not causing obstruction, and then shifting its position closed off the exit to the bladder and therefore blocked the natural drainage with consequent formation of an empyema in the stump of the ureter.

I do not intend to discuss treatment except to mention the fact that most writers on the subject such as Hyman, Hunt, Reid, Latchem and White recommend surgical removal of the infected stump. This was carried out in the case reported in this paper.

SUMMARY AND CONCLUSIONS

Pyoureter and periureteritis occurred seventeen years after nephrectomy for calculous pyonephrosis. The stump of the ureter contained a calculus.

No genitourinary or other symptoms referable to the process were present during these seventeen years.

The patient presented a diagnostic problem of obscure fever of six weeks' duration.

Successful surgical removal was carried out.

It is important to determine at the time of nephrectomy whether the ureteral orifice into the bladder will remain patent. If by the presence of a calculus or stricture free drainage into the bladder is prevented, complete ureterectomy should be carried out to obviate future infection and empyema in the ureteral stump.

PSEUDOEPITHELIOMATOUS HYPERPLASIA IN A CASE
OF MULTIPLE PYODERMA

S. R. MERCER, M.D., FORT WAYNE, IND.
AND M. E. OBERMAYER, M.D., LOS ANGELES

Pseudoepitheliomatous hyperplasia has lately been studied extensively by Winer.¹ His report covers the literature so completely and reviews the theoretical and practical considerations of this difficult problem so thoroughly that these topics need not be discussed here.

The following case is reported because we believe that it illustrates well the practical difficulties intrinsic in the histologic diagnosis of pseudoepithelioma.

REPORT OF CASE

A. S., a white man of native Kentucky stock, aged 50, complained of ulcers on the buttocks of about six months' duration. The lesions started as small painful "spots" and gradually enlarged to cover the entire left buttock and the adjacent part of the thigh and the medial half of the right buttock. The history that the patient gave must be accepted with reservations, because he frequently changed his story. He spent the greater part of his life in various institutions of correction. When free, he was either a broommaker, a gardener or an itinerant cosmetic peddler. Questioning in regard to venereal diseases brought the reply "Yep, doc. I've had all of them many times, and lots of shots—got yellow from them once—lasted three months." The only other illnesses he remembered were childhood diseases.

Fig. 1.—Section from border of ulcer, showing thickening of the epidermis, disruption of basal cell layer, apparent infiltration of dermis with nests of cells and dermal cellular infiltrate. Low magnification.

His general development and nutrition were good. Examination revealed that the skin of the affected area was erythematous and definitely indurated. Within this area were scattered tender, crusted lesions approximately 1.5 to 2.5 cm.

in diameter. Removal of the crusts disclosed ulcers with nonindurated, rolled borders and an uneven, easily bleeding, depressed surface. In addition, small ulcerated lesions of the ecthyma type were present on the elbows and on the anterior surfaces of the ankles and feet.

Fig. 2.—High magnification of figure 1, showing concentric arrangement of cells with keratinized cell types in the center, cellular anaplasia and mitotic figures.

Scattered over the lateral and posterior aspects of the thighs and the anterior portions of the legs were atrophic scars with hyperpigmented borders; their outline was suggestive of healed cutaneous gummas.

A provisional diagnosis of pyoderma, with infectious granuloma of syphilitic or fungous origin as an alternative diagnosis, was made.

The blood count was normal; examination of the blood, including Wassermann, Kahn, Kline and Mazzini tests, gave negative results; the result of the provocative Mazzini test was likewise negative.

Two specimens from the borders of the ulcers were removed for biopsy and examined at the University of Chicago Clinics.

One section showed the features of an infectious granuloma with epidermal proliferation and heavy dermal infiltration, consisting mainly of plasma and epithelial cells, which reached far down into the dermis.

The other section, however, showed the features illustrated in figures 1 and 2. The epidermis was considerably thickened. The basal cell layer was disrupted and the dermis appeared to be infiltrated with nests of cells resembling those of the prickle cell layer. The arrangement of the cells was concentric, with keratinized cell types in the center. Distinct cellular anaplasia was present, and numerous mitotic figures were seen. The dermis appeared to be disrupted and edematous. A cellular infiltrate, composed for the most part of round cells and some plasma cells, was present around the nest of epithelial cells. On the basis of these features a diagnosis of squamous

1. Winer, L. H.: Pseudoepitheliomatous Hyperplasia, Arch. Dermat. & Syph. 42: 856 867 (Nov.) 1940.

cell carcinoma was made. However, since the history of multiple ulceration of comparatively short standing did not seem in agreement with the histologic diagnosis, the section was shown to Dr H Gideon Wells, of the Department of Pathology of the University of Chicago, who confirmed the diagnosis of squamous cell carcinoma.

The incorrectness of the histologic diagnosis was soon brought out by the clinical course of the disorder. The simple local measures employed consisted of sitz baths of a solution of potassium permanganate (1 8,000) several times daily and alternate applications of boric acid ointment, U S P, and of a 2 per cent aqueous solution of methylrosaniline. In addition, several iron compounds and liver extract were administered. The ulcers improved slowly but constantly and were almost entirely healed within a period of twenty weeks, at which time the patient was lost from observation.

The nonmalignant character of the ulcers was also verified histologically by a second biopsy, performed eighteen weeks after the first, the specimen was removed from an area practically contiguous to that from which the first specimen was taken. The second section showed none of the features of squamous cell carcinoma but only those of a nonspecific infectious granuloma.

SUMMARY AND CONCLUSIONS

One of the ulcers in a case of multiple pyoderma with pseudoepitheliomatous hyperplasia at biopsy showed features so suggestive of squamous cell carcinoma that a dermatologist and a pathologist independently made that diagnosis. The practical difficulty of recognizing pseudoepitheliomatous hyperplasia histologically is illustrated.

347 West Berry Street—1930 Wilshire Boulevard

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADDITION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

IT SHOULD BE NOTED THAT FOR THE PRESENT THE COUNCIL ACCEPTS PYRIDOXINE HYDROCHLORIDE ONLY FOR PURPOSES OF STANDARDIZATION AND EXPERIMENTATION. A. C. SMITH, M.D., Acting Secretary

PYRIDOXINE HYDROCHLORIDE.—2-methyl-3-hydroxy-4,5-di (hydroxymethyl) pyridine hydrochloride (vitamin B₆ hydrochloride)—C₈H₁₀O₄N HCl (205.64). Pyridoxine Hydrochloride has the following structural formula

It may be isolated from natural sources or prepared synthetically from ethoxy-acetylacetone and cyanoacetamide.

Actions and Uses.—The nutritive and therapeutic value of pyridoxine hydrochloride has not been definitely established. It has been accepted by the Council for purposes of standardization and experimentation only.

Dosage.—A dose of 5 to 10 mg daily is suggested.

Pyridoxine hydrochloride occurs as a white, odorless crystalline powder which melts with decomposition between 200 and 212 C. Under the polarizing microscope it appears as thick, birefringent rods and broken fragments. When recrystallized from methanol containing a few drops of concentrated hydrochloric acid needle-shaped crystals are obtained which are birefringent and exhibit oblique extinction. In the crystalline state it is stable to light and air. Acidic aqueous solutions are stable and may be heated for thirty minutes at 100 C. (22 Gm per hundred cubic centimeters), slightly soluble in 95 per cent ethanol (11 Gm per hundred cubic centimeters), sparingly soluble in acetone, practically insoluble in ether. Aqueous solutions are acidic (pH about 3.0 for a concentration of 10 mg per cubic centimeter), produce a red color with ferric chloride solution, yield a precipitate with phosphotungstic acid solution and yield a precipitate with silver nitrate solution which is insoluble in nitric acid but soluble in ammonia water. Dissolve a few crystals of pyridoxine hydrochloride in 2 cc of alcohol. Add 2 drops of 10 per cent ammonium hydroxide solution and 1 cc

of 2,6-dichloroquinone chloroimide solution (0.01 per cent in alcohol). A deep blue color forms on standing.

Char. 0.4 Gm of pyridoxine hydrochloride. Boil the charred mass with a mixture of 2 cc of concentrated nitric acid and 8 cc of water, filter, wash with water, evaporate the filtrate to dryness and dissolve the residue in 0.5 cc of tenth normal hydrochloric acid, dilute to 5 cc with water and add 5 cc of hydrogen sulfide solution, any color produced does not exceed that of a blank control containing 0.02 mg of lead (0.005 per cent as lead).

When dried over sulfuric acid, anhydrous calcium sulfate or anhydrous magnesium perchlorate for twenty-four hours, the loss in weight does not exceed 0.2 per cent.

Determine the carbon and hydrogen content by combustion. The carbon content is not less than 46.5 nor more than 46.9 per cent, the hydrogen content is not less than 5.6 nor more than 6.0 per cent. The residue from the carbon hydrogen determination, or from an ash determination, does not exceed 0.05 per cent.

Determine the nitrogen content. The amount found is not less than 6.6 nor more than 6.9 per cent.

Method of Assay for Tablets and Solutions

The following reagents are necessary:

1. **Veronal Buffer.**—Dissolve 18.0 Gm sodium diethylbarbiturate in 200 cc of distilled water and titrate with normal hydrochloric acid to a pH of 7.5 to 7.7, using a glass electrode. Filter off the precipitate of diethylbarbituric acid. (If the buffer is allowed to stand over twenty-four hours, the pH must be readjusted with either normal hydrochloric acid or normal sodium hydroxide to a pH of 7.5 to 7.7.)

2. **Chloroimide Reagent.**—Dissolve 25.0 mg 2,6-dichloroquinone chloroimide in 100 cc of acid free butanol. If the reagent is to be kept for some time, it must be stored in a brown, glass stoppered bottle at refrigerator temperatures, treated thus it is stable for about two weeks.

3. **Standard Solution.**—10.0 mg of dried crystalline pyridoxine hydrochloride is dissolved in exactly 100 cc of absolute alcohol. If the solution is to be used immediately, 95 per cent ethanol may be employed. (In the absence of a microbalance a larger quantity may be weighed and appropriate dilutions made from the more concentrated stock solution.)

Procedure.—Dilute the pyridoxine hydrochloride solutions to be tested to a final concentration in 0.10 mg of pyridoxine hydrochloride per cubic centimeter. In the case of tablets a sufficient number—ten or more—are transferred to a volumetric flask, water added and the flask shaken to disintegrate the tablets. After diluting to the mark the solution is filtered, the first 25 cc discarded and the next 25 cc saved for the test.

In the following procedures the preparation of the standard and unknown must be carried on concurrently to allow the same amount of time for the development of color in the two solutions.

Transfer 5.0 cc of the solution to be tested (after diluting as indicated) to a 50 cc volumetric flask. Add 5.0 cc of the veronal buffer and 20 cc of ethanol.

Prepare a standard comparison solution by transferring 5.0 cc of the standard pyridoxine hydrochloride solution to a 50 cc volumetric flask, adding 5.0 cc of veronal buffer, 15 cc of ethanol and 5 cc of water.

Now add to both solutions 5.0 cc of butanol chloroimide reagent, start timing and shake intermittently for twenty minutes. Dilute to the mark with ethanol and compare in a colorimeter. The pyridoxine hydrochloride found is not less than 93 or more than 107 per cent.

EVIPAL SOLUBLE.—Evipal sodium—Sodium N-methylcyclohexenyl methyl-barbiturate—Sodium 1,5-dimethyl-5-Δ¹-cyclohexenyl barbiturate—Sodium cyclohexenylidimethyl barbiturate—C₁₁H₁₅O₄ N-Na. The sodium salt of 1,5-dimethyl-5-Δ¹-cyclohexenyl barbituric acid.

Actions and Uses.—The actions and uses of evipal soluble are essentially similar to those of pentobarbital sodium except that it is designed only for intravenous use to produce anesthesia of short duration. When injected intravenously it is a quick-acting, general anesthetic with an early recovery period. In the majority of cases consciousness is restored in from fifteen to thirty minutes, depending on the amount of drug injected. Not uncommonly there follows some drowsiness or sleep if the patient is left undisturbed. While the intravenous use of barbiturates is a valuable procedure under certain circumstances it should be undertaken only by those experienced in this field who have had special training in the use of anesthetics of this type. It should not be looked on as an office procedure, adequate facilities should be at hand to combat untoward reactions. Ataxia and transient amnesia may occasionally be encountered. Contraindications are in general those of the barbitol compounds and general anesthetics.

Dosage.—As there is considerable variation in individual reactivity to any of the barbiturates, the dose must be individualized. In general, 2 cc to 4 cc of a 10 per cent solution is required to induce unconsciousness in adults, this is injected intravenously at the rate of 1 cc per ten seconds. An additional 1 cc, or 2 cc may be necessary if relaxation is not obtained with the initial dose, or it may be required during the operative procedure. A total amount of 10 cc of this 10 per cent solution is seldom required for adults, and it cannot be exceeded without danger.

Caution. If the solution is discolored or shows the presence of undissolved particles even though it is freshly prepared, it should be discarded. The powder and solution undergo change on exposure to air and should not be kept for future use.

Manufactured by Winthrop Chemical Co., New York. U S patent 1,947,944. U S trademark 315-515. Ampules Evipal Soluble, 0.5 Gm powder, packaged with or without sterile distilled water.

Ampules Evipal Soluble, 1 Gm powder, packaged with or without sterile distilled water

Evipal soluble occurs as a white crystalline odorless hygroscopic powder, with a slightly bitter taste, very soluble in water freely soluble in alcohol, practically insoluble in ether. An aqueous solution of evipal soluble is alkaline to litmus.

Dissolve about 0.5 Gm of evipal soluble in 100 cc of water, add an excess of diluted hydrochloric acid mix, allow to stand fifteen minutes and collect the resultant cyclohexenylmethyl barbituric acid on a filter, wash with water and dry at 65°C. It melts at 143-146°C.

Transfer about 0.1 Gm of the dried cyclohexenylmethyl barbituric acid to a stoppered cylinder, add 25 cc of water, shake the mixture for one minute, filter through paper and divide into two portions, to one portion add 1 cc of acetic acid and 0.5 cc of water saturated with bromine. An immediate discoloration occurs, to the other portion add 0.1 cc of tenth normal potassium permanganate solution a pale brownish yellow color appears.

Transfer about 0.5 Gm of evipal soluble to a 50 cc Erlenmeyer flask, add 5 cc of water and about 0.4 Gm of *p*-nitrobenzyl chloride dissolved in 10 cc of 90 per cent ethyl alcohol. Attach the flask to a reflux condenser and heat the mixture on a water bath for one half hour. Cool the flask and collect the precipitate on a filter, wash with water, dry at 65°C, dissolve the dry product in 5 cc of chloroform, filter, reprecipitate with alcohol and collect the precipitate, dry at 65°C the melting point of the product is 114-115°C.

Transfer about 0.3 Gm of evipal soluble to a test tube containing 2 cc of water and add dropwise a saturated solution of bromine in water until the color of bromine faintly persists after vigorously shaking the test tube. Pour the contents of the test tube into 100 cc of water, filter through paper, wash with water and dry at 65°C. The melting point of the product lies between 130 and 132°C, with decomposition.

Incinerate about 1 Gm of evipal soluble in a porcelain dish, cool, dissolve the residue in 50 cc of water and divide into two portions. The first portion responds to tests for sodium carbonate. Rinse the porcelain dish with 2 cc of diluted hydrochloric acid, add the rinsings to the second portion and filter through paper. The filtrate yields no coloration or precipitation on saturation with hydrogen sulfide (salts of heavy metals).

Boil about 0.5 Gm of evipal soluble with 5 cc of a 25 per cent sodium hydroxide solution. It is decomposed with evolution of ammonia.

Dissolve about 0.5 Gm of evipal soluble in 10 cc of water and divide the solution into two portions. To one portion add 1 cc of mercuric chloride solution a white precipitate results, insoluble in excess water, soluble in an excess of ammonia, to the other portion add 5 cc of silver nitrate solution a white precipitate results, soluble in excess water, soluble in an excess of ammonia.

Dissolve about 0.5 Gm of evipal soluble in 50 cc of water, add 5 cc of diluted nitric acid, allow to stand for fifteen minutes and filter through paper. Separate portions of 10 cc each of the filtrate yield no opalescence on the addition of 1 cc of silver nitrate solution (chloride), no turbidity on the addition of 1 cc of barium nitrate solution (sulfate).

Add about 0.1 Gm of evipal soluble to 2 cc of sulfuric acid the solution is pale yellow, gradually changing to brown orange (easily carbonizable substances).

Transfer about 1 Gm of evipal soluble accurately weighed, to a glass stoppered cylinder add 50 cc of anhydrous ether, stopper and shake for ten minutes decant the supernatant liquid filter through paper and repeat twice, using 25 cc and 15 cc portions of ether, respectively, utilizing the same filter, evaporate the combined filtrates to dryness in a tared beaker and dry to constant weight at 65°C the residue does not exceed 0.2 per cent (uncombined cyclohexenylmethyl barbituric acid). Dry about 1 Gm of evipal soluble accurately weighed, to constant weight at 65°C the loss in weight is negligible.

Transfer about 0.5 Gm, accurately weighed, of the dried evipal soluble to a tared porcelain dish add 2 cc of sulfuric acid, cautiously ignite until the excess of sulfuric acid has been volatilized repeat the ignition twice with the addition of 1 cc of sulfuric acid, add about 0.5 Gm of ammonium carbonate, ignite to constant weight and weigh as sodium sulfate the percentage of sodium corresponds to not less than 8.5 nor more than 9.4 when calculated to the dried substance.

Transfer about 0.5 Gm of evipal soluble, accurately weighed, to a suitable separator add 15 cc of water followed by the addition of 10 cc of diluted hydrochloric acid, extract the mixture with eight successive portions of chloroform using 25 cc 15 cc and six portions of 10 cc respectively, evaporate the combined chloroform extracts in a tared beaker to dryness in a stream of warm air and dry to constant weight at 65°C the amount of cyclohexenylmethyl barbituric acid corresponds to not less than 91 per cent nor more than 92 per cent, calculated to the dried substance.

Dissolve the cyclohexenylmethyl barbituric acid obtained as above, in 25 cc of previously neutralized alcohol add 25 cc of recently boiled and cooled distilled water and titrate with tenth normal sodium hydroxide solution, using thymolphthalein as an indicator the amount of tenth normal sodium hydroxide consumed corresponds to not less than 98.5 per cent nor more than 101.5 per cent of cyclohexenylmethyl barbituric acid.

THEOPHYLLINE WITH ETHYLENEDIAMINE-U. S. P (See New and Nonofficial Remedies, 1941, p 583)

The following dosage forms have been accepted

Tablets Aminophylline 0.0975 Gm (1/10 grains)

Prepared by E. S. Miller Laboratories, Inc., Los Angeles

Tablets Aminophylline 0.195 Gm (3 grains)

Prepared by E. S. Miller Laboratories, Inc., Los Angeles

Ampul Solution Aminophylline, 2.4% W/V, 10 cc

Prepared by E. S. Miller Laboratories, Inc., Los Angeles

Ampul Solution Aminophylline 2.4% W/V in Ethylenediamine Solution 1% V/V (with Benzyl Alcohol 2% V/V), 2 cc

Prepared by E. S. Miller Laboratories, Inc., Los Angeles

PHENOLSULFONPHTHALEIN (See New and Nonofficial Remedies, 1941, p 230)

The following dosage form has been accepted

Ampuls Phenolsulfonphthalein Solution, 6 mg, 1 cc

Each cubic centimeter of solution contains 6 mg of phenolsulfonphthalein in the form of the monosodium salt

Prepared by Lakeside Laboratories, Inc., Milwaukee

MERCURIC SUCCINIMIDE (See New and Nonofficial Remedies, 1941, p 350)

Cheplin Biological Laboratories, Inc., Syracuse, N. Y.

Vial Solution Mercuric Succinimide, 1/2 grain (0.01 Gm.) in each cc, 30 cc Each cubic centimeter contains mercuric succinimide 0.01 Gm, benzyl alcohol 0.01 cc and glycerin 0.013 Gm in sufficient distilled water to make 1 cc

Ampules Solution Mercuric Succinimide, 1/2 grain (0.02 Gm.), 1 cc Each 1 cc ampule contains mercuric succinimide 0.02 Gm, benzyl alcohol 0.01 cc and glycerin 0.013 Gm in sufficient distilled water to make 1 cc

Vial Solution Mercuric Succinimide, 1/2 grain (0.02 Gm.) in each cc, 30 cc Each cubic centimeter contains mercuric succinimide in sufficient distilled water to make 1 cc

Flint, Eaton & Co., Decatur, Ill.

Ampul Solution Mercuric Succinimide, 0.01 Gm (1/2 grain), 1 cc

LIVER EXTRACT (INJECTABLE) U. S. P-ENDO (See THE JOURNAL, March 29, 1941, page 1391, and Supplement to New and Nonofficial Remedies, 1941, page 12, under LIVER EXTRACT (INJECTABLE) U. S. P-ENDO, 10 UNITS PER CC)

The following dilution dosage forms have been accepted

Liver Extract (Injectable) U. S. P Endo (5 U. S. P units per cc), 1 cc Ampoule

Liver Extract (Injectable) U. S. P Endo (2 U. S. P units per cc), 10 cc vial

THIAMINE HYDROCHLORIDE (See New and Nonofficial Remedies, 1941, p 551)

The following additional dosage forms have been accepted

Tablets Thiamine Hydrochloride, 1 mg, 5 mg, 10 mg

Prepared by Flint, Eaton & Co., Decatur, Ill.

Ampuls Solution Thiamine Hydrochloride, 10.0 mg, 1 cc

Prepared by Flint, Eaton & Co., Decatur, Ill.

Vials Solution Thiamine Hydrochloride, 10 mg per cc, 25 mg per cc and 50 mg per cc in 15 cc vials

Prepared by Flint, Eaton & Co., Decatur, Ill.

I. V. C. Thiamine Hydrochloride Crystalline Tablets, 50 mg and 10 mg

Prepared by the International Vitamin Corporation, New York. No U. S. Patent or trademark.

THIAMINE HYDROCHLORIDE-MERRELL (See New and Nonofficial Remedies, 1941, p 553)

The following dosage forms have been accepted

Thiamine Hydrochloride Tablets Merrell, 50 mg and 100 mg

SODIUM THIOSULFATE (See New and Nonofficial Remedies, 1941, p 503)

The following dosage forms have been accepted

Ampuls Sodium Thiosulfate (Flint, Eaton & Co.), 0.5 Gm (7 1/2 grains), 5 cc

Prepared by Flint, Eaton & Co., Decatur, Ill.

Ampuls Sodium Thiosulfate (Flint, Eaton & Co.), 1.0 Gm (15 1/2 grains), 10 cc

Prepared by Flint, Eaton & Co., Decatur, Ill.

SULFATHIAZOLE (See New and Nonofficial Remedies, 1941, p 519)

Sulfathiazole-Lakeside.—A brand of sulfathiazole-N. N. R.

Manufactured by Lakeside Laboratories, Inc., Milwaukee. No U. S. patent or trademark.

Tablets Sulfathiazole 0.5 Gm (7.7 grains)

TETANUS ANTITOXIN BOVINE (See New and Nonofficial Remedies, 1941, p 437)

The Gilliland Laboratories, Inc., Marietta, Pa.

Tetanus Antitoxin (Bovine), Gilliland—A concentrated and refined antitoxin made from the blood serum of cattle hyperimmunized against the toxin of *Clostridium tetani*. Marketed in packages of one vial containing 1,500 units and in packages of one vial containing 10,000 units.

RINGER'S SOLUTION (See New and Nonofficial Remedies, 1941, p 389)

Ringer's Solution in Vacoliter Container Each hundred cubic centimeters contains sodium chloride U. S. P. 0.7 Gm, potassium chloride N. F. 0.03 Gm and calcium chloride U. S. P. 0.025 Gm. Marketed in bottles (Vacoliter containers) of 500 cc and 1,000 cc.

Prepared by Baxter Laboratories, Inc., Glenview, Ill., and Don Baxter, Inc., Glendale, Calif.

RIBOFLAVIN (See New and Nonofficial Remedies, 1941, p 553)

Mead's Riboflavin Tablets 1 mg

Prepared by Mead Johnson and Company, Evansville, Ind.

ENROLMENT FOR SERVICE IN THE ARMY AND NAVY

Last week The Journal published an urgent request to all physicians of the United States to fill out the questionnaire published in that issue and mail it at once to Dr. Sam F. Seeley, Executive Officer of the Procurement and Assignment Service, Washington, D. C., indicating their availability to serve the nation in the present emergency. The response to this call to the medical profession to date has been highly gratifying. The following statement to that effect, with additional instructions, has been received from the Directing Board of the Procurement and Assignment Service:

The response of the physicians of the country to the Procurement and Assignment Service request for enrolment of those now ready for immediate service in the army or the navy is highly gratifying. All names are being processed, and those who meet the present demands of the Surgeon Generals will receive application forms and authority to appear for physical examination at an early date. All who are now ready for immediate duty should forward applications to the Procurement and Assignment Service at once. It is not the intention of the Procurement and Assignment Service to register every physician, dentist and veterinarian at the present time. Only those available for immediate assignments should register at this time. The physical requirements of all military, governmental, industrial and civil agencies will be published in national and state journals immediately. On the basis of this information every physician, dentist and veterinarian will be able to make a self appraisal of his physical qualifications. Within a few weeks the Procurement and Assignment Service will mail to all individuals a form on which they will be asked to state their preferences for assignment to all agencies of national defense which require medical, dental and veterinary personnel and for service in communities in public health and other civil categories. In this way every physician, dentist and veterinarian of the country will be able to lend maximum support to the national emergency. In order to meet the expanding needs of the military services, every physician immediately available for

duty should mail his application blank to the Procurement and Assignment Service at once. All others will be given an opportunity to volunteer in the near future.

Executive Officer.

CALCIUM AND THE METABOLISM OF LEAD

Modern industry raises many questions in fields related to medicine. One of the problems of growing interest concerns the increased possibility of lead poisoning; paint pigments, tetraethyl lead in motor fuels, and spray materials used on fruits and vegetables are a few of many possible sources of exposure to lead under current ordinary living conditions. Numerous studies with a variety of analytic procedures have shown that practically all the body tissues contain measurable amounts of lead.

Of compelling interest is the similarity between the distribution and mobilization of lead and that of calcium and phosphorus. Experience with physicochemical models indicates that lead is transported in the blood as the secondary phosphate but is deposited in the bones as the insoluble tertiary phosphate.¹ Aub and his co-workers² have shown that not only is lead stored in the trabeculae of the long bones, as is the readily available calcium, but solution of parathyroid will mobilize this lead and the calcium in a parallel manner. Both roentgenographic evidence³ and the results of intravenously administered radioactive lead⁴ indicate its deposition and mobilization from those structures where shifts in calcium are likewise taking place. These and similar observations have led to the conception that lead and calcium are strikingly similar in their metabolism. In the toxic episode of lead poisoning it is advisable to immobilize the metal in the bones by promoting the concomitant deposition of calcium.⁵ Subsequent treatment with acidifying agents such as ammonium chloride will bring forth the lead and the calcium into the blood stream, and deleading thus occurs.

With the organism in negative calcium balance such as occurs on a calcium-poor regimen, it might be expected that administered lead would be prevented from localizing in the bony trabeculae. However, a recent study by Shields and Mitchell⁶ confirms earlier similar work that diets low in calcium or in phosphorus or in both promote increased lead retention. That this is due to circumstances within the gastrointestinal tract

was shown by Lederer and Bing;⁷ they found that the level of calcium in the ration exerts no influence whatever on the retention of lead when a lead salt is administered parenterally.

On the basis of current evidence, it appears that the mobilization of lead already deposited in the bones shows a striking parallel to the mobilization of calcium and that the absorption of lead from the intestine is influenced by the level of calcium in the diet. The deposition of lead in the bones appears to take place in inverse relation to that of calcium. Obviously, further study in this important field is necessary. From the point of view of public health, it is reassuring that an adequate intake of calcium and phosphorus presumably tends to protect the body against the assimilation of the small amounts of lead that are unavoidably taken into the gastrointestinal tract under ordinary conditions.

ISOIMMUNIZATION: ITS ROLE IN TRANSFUSION REACTIONS AND IN FETAL ERYTHROBLASTOSIS

For long it was believed that hemolytic transfusion reactions do not occur when patient and donor are alike with respect to the Landsteiner blood groups O, A, B and AB. In a recent paper, Wiener and Peters⁴ pointed out that there are two classes of patients for whom this dictum does not hold. The first class includes patients who have been receiving repeated blood transfusions which have stimulated the appearance in the patient's serum of immune isoantibodies directed against the donor's cells, owing to blood factors unrelated to the four blood groups. For the second class of patients this explanation does not hold, as this class includes persons who have never previously undergone transfusion. All members of the second class, however, were found to be female patients ante partum or post partum. Wiener and Peters have suggested that these also represent cases of isoimmunization, the fetus in utero supplying the foreign antigen. This explanation had previously been proposed by Levine and Stetson² to explain a transfusion reaction in a case of pregnancy studied by them.

Of the blood properties which can give rise to isoimmunization, other than the factors A and B which determine the four Landsteiner blood groups, Wiener³ has found the Rh factor most important. While isoimmunization as a result of repeated transfusion and in pregnancy is a relatively uncommon phenomenon, the Rh factor is the most apt to be responsible when it occurs. The Rh factor was first described by Land-

steiner and Wiener⁴ in 1940 and was so named because it was detected with an immune serum against rhesus blood. The factor is present in the blood of 85 per cent of persons in the normal population, regardless of the blood groups. As Wiener and Peters have shown, transfusions of Rh positive blood to Rh negative persons is well tolerated in the great majority of persons, but with occasional patients such transfusions give rise to isoimmunization. After the first transfusion in these cases the donor's blood is eliminated from the patient's circulation with few or no symptoms. Later, however, anti Rh isoantibodies appear in the patient's serum, so that subsequent transfusions of Rh positive blood may give rise to severe or even fatal reactions. Landsteiner and Wiener⁵ have shown that the property Rh is inherited as a simple mendelian dominant. It is possible for an Rh negative mother to have an Rh positive child, namely, if the father is Rh positive. While such matings occur in about one seventh of all marriages, isoimmunization of the mother by the blood of the fetus is far less frequent. In certain rare instances, owing perhaps to some imperfection in the placenta, fetal blood escapes into the maternal circulation. As a result of such small repeated "transfusions" of Rh positive fetal blood, Rh negative mothers may produce anti Rh antibodies. Should the mother require a blood transfusion and the anti Rh isoantibodies not be detected in the cross match tests, a hemolytic reaction may result. A difficulty in the tests is that the agglutination reactions of many serums containing anti Rh isoagglutinins are not strong, but positive and negative reactions are more readily distinguished from the appearance of the sediment in the tests. Landsteiner and Wiener⁵ describe an improved method for obtaining anti Rh immune serums by injecting guinea pigs with rhesus blood.

Shortly after the report by Wiener and Peters, Levine and Katzin⁶ pointed out the close association between isoimmunization in pregnancy and pregnancy complications; Levine, Katzin and Burnham⁷ suggested that this might be the cause of fetal erythroblastosis. If an Rh negative mother with an Rh positive fetus should produce anti Rh isoantibodies and these should filter back into the fetal circulation, they might have a destructive effect on the blood of the fetus and in this way give rise to symptoms of icterus gravis neonatorum or congenital hemolytic anemia. Subsequent studies in a larger series of cases have established the correctness of this theory beyond doubt. While only 15 per cent of persons in a random population are Rh negative, 90 per cent of mothers of erythro-

blastotic infants have proved to be Rh negative.⁸ Moreover, in many of the mothers' serums anti Rh agglutinins were detectable.

While the Rh factor has proved to be responsible for the great majority of instances of hemolytic reactions following transfusions of blood of the homologous group, a few instances have occurred in which this explanation did not hold. In these much less frequent cases other blood factors have been found to be at fault. Thus, Wiener⁹ reports 2 instances of isoimmunization of A₂ patients against A₁ blood, 1 by repeated transfusion, the other as a result of pregnancy; Wiener and his collaborators have also observed the appearance of anti O isoagglutinins in the serum of a group AB patient given group O blood; and anti P agglutinins have been found in the serum of a P negative patient given P positive blood.¹⁰ Similarly there are cases of fetal erythroblastosis in which the mother is Rh positive. Here it has been suggested that blood factors other than Rh may be responsible. For example, Levine and Polayes¹¹ have described an instance of isoimmunization in pregnancy in which the mother's serum contained an isohemolysin with reactions unrelated to Rh or any blood factor previously described. At times the situation may be complicated, as in a case recently reported by Wiener and Forer,¹² in which the serum of a group O person had two irregular agglutinins in it, one against the Rh factor, the other against agglutigen M. For this patient only group O donors with blood of type N and lacking the Rh factor could be used. Two such donors were found among 90 group O donors tested, transfusions proving successful.

The observations of Wiener and his collaborators on intragroup hemolytic transfusion reactions and of Levine and his collaborators on fetal erythroblastosis are significant from the point of view of the individuality of human blood. With the factors A₁, A₂, B, M, N, P and Rh as many as seventy-two distinct types of human blood can be identified. With the additional factors that are identifiable with post-transfusion serums and serums from mothers of infants with fetal erythroblastosis, the number of subdivisions of human blood possible is further increased, as had also been shown with the aid of irregular isoagglutinin in normal human serums.¹³ As examples one might mention the special hemolysin observed by Levine and Polayes¹¹ in a pregnancy serum and the observations of Wiener⁹ that there are at least two sorts of Rh factor.

Current Comment

1942 DUES NOW PAYABLE

For the convenience of Fellows and subscribers who have not paid the 1942 dues, a colored reminder slip is enclosed in this issue of *THE JOURNAL*. It takes the place of a personal statement, and its use by those who have not yet paid for 1942 will result in a tremendous saving of postage and clerical work in the Headquarters office. The slip is cut so that when folded it forms a ready addressed, ready stamped envelop for check, money order or draft. It lists not only *THE JOURNAL* but all the special journals of the Association, with their respective subscription prices—likewise *Hygeia*, the Health Magazine. Thus payment for all publications desired may be covered with one remittance. If you have already paid for 1942, please disregard the slip.

BEHAVIOR OF GLYCERIN IN THE ANIMAL ORGANISM

Glycerin is widely employed in pharmaceutical preparations, perhaps more frequently than any other substance except water. Any toxic properties which it may possess, therefore, are important. Deichmann¹ concludes that glycerin is absorbed from the peritoneum, the gastrointestinal tract and subcutaneous tissue but that its penetration of the intact skin appears to be negligible. Toxic doses of glycerin produce characteristic signs and symptoms and in sufficient quantities can cause death. Intravenous injection of even small doses results in a transient fall in the arterial blood pressure and an increased rate and magnitude of respiration. A lethal oral dose will produce a slowly failing circulation, while a lethal intraperitoneal injection produces a stimulation of respiration and finally a sudden drop of arterial blood pressure. Death is due to the combined effects of failing circulation and respiration. Diuresis appears to be more pronounced after oral than after subcutaneous administration. A portion of absorbed glycerin is transformed in the organism into dextrose and subsequently into glycogen. Glycerin appears to exert a protein-sparing action if administered in concentrations well below the toxic level. The pathologic changes reported in cases of experimental glycerin poisoning are those of acute toxic damage to the liver, kidneys and lungs. The gastrointestinal tract may suffer after the administration of large oral doses, and the subcutaneous tissue may develop pronounced local damage at the site of injection. Although the toxic effects of glycerin as summarized are impressive, it must be pointed out, as Deichmann did, that there are only two cases on record in which glycerin has been known to produce poisoning; these were in children. The toxic effects of this substance, therefore, must be considered as clinically important only in the event of gross overdosage or in the presence of hypersensitivity.

MEDICAL PREPAREDNESS

In this section of The Journal each week will appear official notices by the Committee on Medical Preparedness of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medical preparedness, and such other information and announcements as will be useful to the medical profession.

INFLUENZA

Circular Letter No. 124

The following statement summarizing our present concepts of influenza has been prepared for the Surgeon General by the director of the Commission on Influenza of the Board for the Investigation and Control of Influenza and other Epidemic Diseases in the Army:

1. *Definition.*—Influenza is an acute respiratory disease of virus origin which occurs almost annually in epidemics of varying severity. Two distinct types (types A and B) of virus have been identified; others are suspected. The diagnosis should not be limited to outbreaks of high mortality, such as that of the autumn of 1918. The presence of influenza should be suspected when an undue incidence of unidentified, febrile, upper respiratory disease is encountered.

2. *General Features.*—The usual epidemic is characterized by its sudden appearance in a cantonment, its rapid spread to a peak in from three to four weeks, attacking from 10 to 40 per cent of the population, its low mortality, and its prompt subsidence in from six to eight weeks after onset.

In the average patient the onset is sudden, with chills or chilliness, pharyngeal irritation, generalized aches, prostration and slight dry cough. Respiratory symptoms are not prominent. The temperature reaches 100-103 F., and leukopenia or absence of leukocytosis is the rule. The febrile course lasts from three to five days, followed by relatively prompt recovery except for residual fatigue. An exaggeration of fever or an increase in severity of symptoms indicates the probability of respiratory complications, which vary from tracheitis and bronchitis to extensive pneumonia and empyema.

Complications are usually due to secondary bacterial invaders. The mortality varies with the nature and virulence of the bacterial agents. There may be rapidly fatal cases in which the virus infection is accompanied from the onset by bacterial infection; but more commonly the bacterial complications develop about the time of convalescence from the primary disease.

The virus can be recovered in experimental animals and from the nose and throat secretions of infected individuals. Tests with the patient's serum may be used to identify the disease by demonstrating a rise in antibodies specific for the type of virus present. Immunity develops in convalescence and is effective for an indefinite period, probably longer than is usually assumed.

Approximately one fourth of a population may undergo subclinical infection and during the epidemic period serve as important agents in the transmission of infection.

3. *Control.*—(a) *General Measures:* General control measures should be directed not only toward the prevention of the transmission of influenza virus but also toward the protection of incipient cases and early convalescents from secondary infection with pathogenic bacteria. The virus of influenza is transmitted through the upper respiratory tract by direct droplet infection from an infected individual or by indirect infection with discharges from his respiratory tract. Crowding is a most important factor in the spread of the disease. In the presence of an epidemic, unnecessary congregation in mess halls, recreation centers or barracks should be eliminated, and existing regulations concerning ventilation and bed space in barracks and hospitals should be carried out. If the epidemic is severe, working quarantine of small units may be desirable.

New or unseasoned troops should be segregated, and the transfer of troops to and from infected camps should be discouraged. The transfer by train or transport of bodies of troops infected with influenza is particularly hazardous. Their close

association under such conditions will result in the infection of many who would otherwise escape and in a high incidence of complications and deaths which otherwise would be avoided.

The control measures prescribed in paragraphs 2, 3 and 10, AR 40-220, should be strictly enforced. The admission and general management in hospital is clearly outlined in AR 40-245.

(b) *Specific Measures:* At present no specific control measure has been established, although vaccination methods are under investigation.

4. *Treatment.*—The treatment in uncomplicated cases of influenza is at present symptomatic. There is no evidence that chemotherapy influences the primary virus disease. The patient should be kept warm in bed for forty-eight hours after his temperature has returned to normal. Cold air frequently aggravates the irritation of the respiratory passages. Steam inhalations and soothing cough mixtures with codeine often relieve a persistent distressing cough. Mild antipyretics and sedatives may be used, but narcotics other than codeine are generally contraindicated. Fluids should be given to 3,000 cc. or more daily. The bowels should be regulated when necessary with mild cathartics or enemas. A soft diet can be given as soon as the patient's appetite will tolerate it.

The patient should resume his normal activities gradually. When secondary bacterial invaders are prevalent, protective isolation for a week or more after recovery should be given. Any unexplained rise of temperature or a return of fever should be interpreted as the onset of pulmonary disease due to pathogenic bacteria. Under these conditions adequate measures for the diagnosis of pneumonia and the determination of the infecting bacterial agent should be instituted. Chemotherapy or other available types of therapy directed against the invading bacterium should be used.

By order of the Surgeon General:

JOHN A. ROGERS,
Lieutenant Colonel, Medical Corps,
Executive Officer.

FIRST AID INSTRUCTORS—RED CROSS APPEALS FOR FUNDS

The American Red Cross has sent to San Francisco twenty experienced first aid field representatives who were dispersed at once to strategic points and set to work training lay instructors in first aid throughout the Pacific Coast states.

The lay instructor's course covers forty-five hours of class work and practical application of first aid. For those who already hold Red Cross standard and advanced first aid certificates, this period is reduced to fifteen hours. Those who qualify as instructors are authorized to teach both standard and advanced courses in emergency care of the injured. Red Cross first aid certificates will be awarded to those who successfully complete the latter courses. Doctors who are graduates of recognized medical schools may receive an instructor's appointment from the Red Cross on application to National Headquarters in Washington, D. C., or to the area headquarters in San Francisco, St. Louis and Alexandria, Va.

The Red Cross now has more than thirty-five thousand first aid instructors throughout the country who are busy meeting the demands for training in their local communities. During the past year upward of a million persons received first aid training from Red Cross instructors. Of these about one hundred thousand were residents of California, Oregon, Washington, Idaho, Utah, Arizona and Nevada.

First aid instruction is one of the Red Cross activities on behalf of civilian defense. During the past year local chapters have been organizing and training volunteer first aid detachments to be ready for immediate service in industrial establishments and residential areas in case of explosion, fire, sabotage or other incidents requiring the services of first aiders. Every effort is being made to protect defense industries by means of these first aid detachments. First aid instruction is also being furnished by the Red Cross to soldiers and sailors. This work, which embraces every conceivable type of morale building activity, among the men in uniform as well as their families, has been greatly expanded during the past year.

Because of the heavy financial burden occasioned by its war activities, the Red Cross has appealed for a special fund of \$50,000,000.

RESERVE COMMISSIONS FOR MEDICAL STUDENTS

The National Headquarters of the Selective Service System stated January 1 that Brig. Gen. Lewis B. Hershey, director of Selective Service, has advised all local boards through their state headquarters that third and fourth year students in acceptable medical schools and first year interns may obtain reserve commissions in the Army or Navy and then will be permitted to complete their medical training, including one year of internship, before being ordered to active duty. Such medical students and interns may be deferred by their local boards in class II-A pending receipt of their commissions, but all who are eligible for a commission and do not apply may be considered for classification in class I-A if they are not deferred for other reasons and are found physically qualified for general military service.

Third and fourth year medical students and interns who are rejected after applying for commissions, and also first and second year medical students and those registrants who have been accepted as students in a medical school, may be deferred in class II-A as long as their school officials certify that they give indication that they will become qualified medical practitioners, General Hershey said. He emphasized, however, that no group deferment is permissible under the law and that each case must be decided by a local board on the facts concerning the individual registrant involved.

Medical students and interns accepted by the Army are given commissions as second lieutenants pending graduation when they become first lieutenants in the Army Medical Reserve Corps. Those accepted by the Navy are commissioned as ensigns until graduation, when they become lieutenants (junior grade) in the Navy Medical Reserve Corps.

BRITISH AMERICAN AMBULANCE CORPS

Since the entrance of the United States into the war and after consultation with representatives of the allied governments, the British American Ambulance Corps has decided to concentrate its efforts in the future on supplying ambulances and a limited number of mobile canteens, leaving to other relief organizations the sending of other essential medical supplies. However, contributions will be accepted for stretchers, blankets and first aid cases to the extent that they are needed to equip ambulances. The British American Ambulance Corps will continue with no diminution of effort to raise funds for ambulances for the allied cause and will bend every effort to raise not only the number now needed but a sufficient number to use as a reserve to meet without delay any emergency that may arise. Ambulances will not be accepted, therefore, for any particular country or front. Only one particular type of ambulance will be purchased, and it is so constructed that it can do service in both tropical and cold climates. The sides and top are demountable and may be packed flat in the chassis in order to reduce space required for shipping. This standardized type of ambulance is sturdy, will attain a speed of 60 miles an hour on good roads and will stand up under desert or other rough conditions. These ambulances cost \$2,000 each.

Recently the British American Ambulance Corps has had demand from several cities in the United States for ambulances and a few weeks ago had a request from London for two hundred and fifty-six ambulances to serve with the Royal Air

Force as a result of the great expansion recently in the Royal Air Force in airplanes and personnel and not proportionately in its ambulance service. Ambulances are not included under the terms of the lend-lease bill. The ambulances donated by groups, corporations or clubs may be marked with any inscription the donor desires, but a promise cannot be made that they will be sent to any particular location.

PERCENTAGE OF CALIFORNIA REGISTRANTS REJECTED

The final figures showing the results obtained by the California boards and their physicians under the old plan of "primary selective service medical examination and classification" before presenting registrants to army examiners at induction stations, are as follows:

Of 60,839 selectees presented to induction stations 5,430 were rejected there (8.92 per cent).

Rejections for physical and mental reasons (excluding illiterates)	8.33%
Rejections for reasons other than physical or mental (includes illiterates)	0.59%

Percentage of rejections for the state..... 8.92%

Breakdown of the 8.92 per cent rejected:

	Per Cent
Eyes (vision principally).....	11.5
Teeth (number, pyorrhea, malocclusion).....	9.5
Weight (mostly underweight, very few overweight).....	4.0
Ear (chronic catarrhal otitis media, membrane).....	7.5
Cardio-vascular (heart, blood pressure, pulse).....	3.5
Spine joints.....	3.0
Genito-urinary (venereal, gonorrhea, syphilis, testicle)....	5.0
Abdominal organs (hernia, gallbladder, appendix, rectum)...	5.5
Nose, mouth (larynx, septum).....	2.5
Neuropsychiatric.....	16.5
Extremities (digits, muscles, pes planus, varicose veins, fractures).....	14.0
Lungs.....	9.5
Endocrine (and skin).....	2.0
Other than physical (illiteracy, felonies, dishonorable discharge, inaptitude).....	6.0
	100

ARMY HOSPITAL NAMED FOR GENERAL DARNALL

The hospital leased by the War Department from the commonwealth of Kentucky at Danville has been designated as "Darnall General Hospital" in honor of the late Brig. Gen. Carl Rogers Darnall, who died in Washington, D. C., Jan. 18, 1941. General Darnall was born in Texas on Dec. 25, 1867 and graduated from Jefferson Medical College in 1890. He entered the military service on Oct. 27, 1896 and his first service was at Fort Clark, Texas, as medical officer with the Twenty-Third Infantry. Later he commanded the military hospital at Iloilo, Philippine Islands. He then served from 1903 to 1913 as secretary of the faculty and instructor at the Army Medical School, Washington, D. C. During the first World War he served as executive officer in the Surgeon General's Office. In 1929 he was appointed Assistant Surgeon General with the rank of brigadier general and was serving in this capacity at the time of his retirement in 1931. General Darnall was awarded the Distinguished Service Medal for organizing and administering the Supply Division of the Medical Department during the World War. He was credited with originating the use of liquid chlorination of water when he was at the Army Medical School as professor of chemistry.

MEDICAL DEFENSE MEASURES IN THE CHICAGO AREA

At a meeting of the defense medical advisory council appointed by the mayor of Chicago, the president of the Chicago Board of Health, Dr. Herman N. Bundesen, announced the creation of a 100 mile emergency medical zone for Chicago and vicinity, including Cook, DuPage and Lake counties in Illinois and part of Lake County in Indiana. The defense medical advisory council will coordinate in this area all hospitals, dispensaries, first aid stations and training stations. The major defense of the medical defense plan called for the organization of two field units for each hospital, organization of emergency

ambulance service, the conversion of trucks into ambulances, the creation of a blood reserve, a campaign for typhoid vaccination and the inventory of all hospitals in this area, with a tabulation of the bed capacity, x-ray equipment, respirators, operating rooms and laboratories.

Chicago's first free ambulance service and mobile operating room equipped for catastrophes and emergencies went into operation on December 17 as a unit of Chicago's only all Negro hospital, Provident Hospital. This service is sponsored by the hospital as a defense measure. There will be two ambulances in this service, one with facilities for transporting 5 patients and equipped to care for 100 patients at the scene of accidents. Its special equipment includes not only four doctors, four nurses and equipment for performing operations in the field but also portable fire fighting apparatus, wrecking tools and an acetylene torch.

The officers of the various women's clubs presented to Mayor Kelly on December 16 the names of thirty-five thousand women who offered their services for defense work, and the work of classifying these women for the various chores was begun at once.

ANNUAL MEDICOMILITARY SYMPOSIUM ON NUTRITION

The annual medicomilitary symposium in the second military area will be held on Tuesday, January 13, at 8:30 p. m. in room 1316X at 90 Church Street, New York City, the general theme of the evening being nutrition in the army. Physicians, dentists, veterinarians, nurses, dietitians, students of professional schools and nutrition experts are cordially invited, as are representatives of the American Red Cross. Lieut. Col. James A. Tobey, Sanitary Corps, will discuss "Nutritional Problems in the Army," Major Louis Griessman of the veterinary reserve "Inspection of Foods in the Army," Col. Samuel A. Cohen of the Medical Corps "The Army Medical Officer and Nutrition," Col. Hyman I. Teperson of the Medical Corps "The Roentgen Ray in the Diagnosis of Nutritional Disorders" and Col. John L. Kantor of the medical corps will give a general summary. Lieut. Col. J. K. Surls of the medical corps will preside. Col. Milton I. Strahl of the medical reserve is chairman of the executive committee. There will be exhibits on army nutrition. The banquet which had been planned for this meeting has been canceled because of the emergency.

OFFICERS, SAILORS AND EMPLOYEES DONATE AMBULANCES

On Dec. 10, 1941 a cavalcade of twelve ambulances, Norfolk's newest gift to the British American Ambulance Corps, left for the United States Naval Base at Norfolk, Va., where they were officially presented to William V. C. Ruxton on the following Friday. The \$24,000 necessary to purchase these ambulances came as a donation from the officers, enlisted personnel and civilian employees of the Norfolk Navy Yard. The campaign was conducted under the direction of Mr. Herbert J. Gerst, British American Ambulance Corps chairman for Norfolk, with the cooperation of Admiral Manley H. Simons of the Navy Yard. In addition to the twelve ambulances the British American Ambulance Corps will receive an additional \$2,000 for an ambulance previously donated by the citizens of Norfolk in memory of Lieut. Comdr. Heywood L. Edwards, who went down with the U. S. Destroyer *Reuben James*.

THE ARMY MEDICAL DEPARTMENT

The history of the Medical Department of the U. S. Army commences with the siege of Boston in 1775. The Second Provincial Congress of Massachusetts Bay provided for examination of persons seeking appointment as surgeons in the colonial forces. Two surgeons and two surgeon's mates were allowed to a hospital, and one surgeon and two mates for a regiment in the field. No method for the evacuation of battle-field casualties existed, and none was perfected until the Civil War, when a surgeon of the Union forces, Jonathan Letterman,

devised a system that has become the basic pattern of the field medical service of all the great powers.

In the first issue of Army Regulations, in 1779, the provisions governing medical service consisted of little more than an injunction to provide sick and wounded soldiers with fresh straw on which to lie, and prescribed, in event of death, the procedure to be followed.

The vast army medical organization of today is equipped and trained for field service with hospitals costing \$160,000,000 and with a budget of \$85,000,000 for the current year. However great the changes since the Revolutionary War, the mission of the Medical Department endures unaltered. Army Regulations describe this mission as "conservation of man power." The accomplishment devolves on three factors: (1) selection and enrolment of those physically fit for military duty, (2) maintenance of health of military personnel by application of preventive medicine and (3) furnishing to the disabled such aid in the form of evacuation and hospitalization as will speedily restore them to health and fighting efficiency.

REFRESHER COURSES FOR NURSES

Graduate nurses in the Detroit area who have not recently been active may review their professional skills in a course to be given by Wayne University at St. Mary's and Evangelical Deaconess Hospitals, Detroit, beginning January 12. One hundred and sixty-one persons have already taken advantage of five similar courses, already completed. There are no fees, as funds have been made available by the State Board of Control for Vocational Education and the W. K. Kellogg Foundation. Applicants must be graduate nurses living in Michigan. Registrations are now being taken by Mrs. Lulu St. Clair Blaine, director of the Community Nursing Bureau and registrar for the course, at 51 West Warren, Detroit.

BRITISH WAR RELIEF ASSOCIATION OF NORTHERN CALIFORNIA

The British War Relief Association of Northern California reports that at the end of another year only one shipment among large quantities of medical and surgical supplies that have been shipped to the British Red Cross has failed to reach its destination. Through the cooperation of the San Francisco County Medical Association, dried blood plasma has been sent to the British commands in Singapore and Hongkong, and portable transfusion kits were placed on board H. M. S. *Liverpool* and *Orion*. As an example of the interest in British war relief in northern California, Dr. John R. Upton cites the Hanford Union High School, whose gift largely made it possible to place the transfusion kits aboard the *Orion*.

SYMPOSIUM ON MILITARY MEDICINE

The Long Island College of Medicine, Brooklyn, sponsored a symposium on military medicine, December 3. The speakers were:

Rear Admiral Charles M. Oman, M. C., U. S. Navy, commanding officer, U. S. Naval Medical Center, Washington, D. C., Medical Tactics as Applied to Naval Warfare.

Capt. Paul M. Albright, M. C., U. S. Navy, Washington, D. C., Eyes of the Navy (illustrated with sound film).

Dr. Philip D. Wilson, New York, Fractures in Modern War.

Capt. Dickinson S. Pepper, M. R. C., U. S. Army, Washington, D. C., The Medical Student and the Military Service.

Comdr. Page O. Northington, flight surgeon, U. S. Navy, New York, Aviation Medicine.

OFFICE OF SURGEON GENERAL MOVED

The office of the Surgeon General of the United States Army in Washington, D. C., has been moved from the new Social Security Building, Fourth and C streets S.W., to 1818 H Street N.W.

ORGANIZATION SECTION

OFFICIAL NOTES

FOURTH ANNUAL CONGRESS ON INDUSTRIAL HEALTH

Sponsored by the Council on Industrial Health of the American Medical Association, January 12-14, at the Palmer House, Chicago: Stanley J. Seeger, M.D., Chairman, Texarkana, Texas; Harvey Bartle, M.D., Philadelphia; Leverett D. Bristol, M.D., New York City; Warren F. Draper, M.D., Washington; Philip Drinker, Boston; Leroy U. Gardner, M.D., Saranac Lake, N. Y.; Raymond Hussey, M.D., Baltimore; Henry H. Kessler, M.D., Newark; Anthony J. Lanza, M.D., New York City; Robert T. Legge, M.D., Berkeley, Calif.; C. W. Roberts, M.D., Atlanta; Clarence D. Selby, M.D., Detroit, and C. M. Peterson, M.D., Secretary, Chicago.

MONDAY MORNING, 9:00

REGISTRATION. NO FEE. RED LACQUER ROOM

MONDAY MORNING, 9:45

STANLEY J. SEEGER, M.D., PRESIDING

Report of the Council on Industrial Health.

STANLEY J. SEEGER, M.D., Texarkana, Texas.

Medical Aspects of Vocational and Industrial Training.

W. A. SAWYER, M.D., Rochester, N. Y.

Chairman, Committee on Industrial Health, Section on Preventive and Industrial Medicine and Public Health, American Medical Association.

The Physiology of Work.

A. C. IVY, M.D., Chicago.

Professor of Physiology, Northwestern University School of Medicine.

LECTURE ON INDUSTRIAL MEDICINE TUBERCULOSIS IN INDUSTRY—A RESUMÉ

LEROY U. GARDNER, M.D., Saranac Lake, New York.

Director, The Saranac Laboratory for the Study of Tuberculosis.

Procurement and Assignment of Physicians for Industry.

SAM F. SEELEY, M.D., Washington, D. C.

Executive Officer, Procurement and Assignment Service, Office of Defense Health and Welfare Services.

RED LACQUER ROOM

MONDAY AFTERNOON, 2:30

WARREN F. DRAPER, M.D., PRESIDING

A Dental Program for Industry.

R. M. WALLS, D.D.S., Bethlehem, Pa.

Chairman, Committee on Economics, American Dental Association.

Industrial Dermatoses.

A Report by the Committee on Industrial Dermatology, Section on Dermatology and Syphilology, American Medical Association.

C. GUY LANE, M.D., Chairman

CHARLES C. DENNIE, M.D.

JOHN G. DOWNING, M.D.

HARRY FÜRSTER, M.D.

EDWARD A. OLIVER, M.D.

MARION SULZBERGER, M.D.

The Panel System in Workmen's Compensation Administration.

DAVID J. KALISKI, M.D., New York City.

Director, Committee on Workmen's Compensation, Medical Society of the State of New York.

Mass Roentgenography of the Chest for the United States Army.

MAJOR ALFRED A. DE LORIMER, M.C., Washington, D. C.

Director, Department of Roentgenology, Army Medical School.

RED LACQUER ROOM

MONDAY AFTERNOON, 2:30

LEVERETT D. BRISTOL, M.D., PRESIDING

SYMPOSIUM ON UNDERGRADUATE INDUSTRIAL MEDICAL EDUCATION

Present Problems in Curriculum Adjustment.

RAYMOND B. ALLEN, M.D., Chicago.

Executive Dean, Chicago Colleges, University of Illinois.

Industrial Health—A Separate Discipline.

T. LYLE HAZLETT, M.D., East Pittsburgh, Pa.

Professor of Industrial Hygiene, University of Pittsburgh School of Medicine.

Correlation of Industrial Hygiene Instruction with Other Clinical Training.
DONALD E. CUMMINGS, Denver.
Director, Division of Industrial Hygiene, University of Colorado School of Medicine and Hospitals.

The Industrial Clinical Clerkship.

FRED J. WAMPLER, M.D., Richmond.

Professor of Preventive Medicine, Medical College of Virginia.

Industrial Experience in the Internship.

WILL F. LYDN, M.D., Chicago.

Assistant Professor of Surgery, University of Illinois College of Medicine.

The Occupational Disease Clinic.

MILTON H. KRDENBERG, M.D., Chicago.

Assistant Professor of Bacteriology and Public Health, University of Illinois College of Medicine.

ROOM 17

MONDAY EVENING, 6:30

STATE SOCIETIES DINNER AND ROUND TABLE

ANTHONY J. LANZA, M.D., PRESIDING

An informal dinner and round table discussion, intended primarily for committees on industrial health in state and county medical societies, will be held. Topics and discussion leaders will be:

Professional Relations.

ANTHONY J. LANZA, M.D., New York City.

Chairman, Committee on Professional Relationships, Council on Industrial Health, American Medical Association.

Industrial Health and the War.

CLARENCE D. SELBY, M.D., Detroit.

Chairman, Subcommittee on Industrial Health and Medicine, Health and Medical Committee, Federal Security Agency.

Visiting Nurses in Industry.

MISS JOANNA JOHNSON, R.N., Milwaukee.

Chairman, Industrial Nursing Section, National Organization for Public Health Nursing.

Progress in Official Agencies.

J. J. BLOOMFIELD, Bethesda, Md.

Chief, States' Relations Section, U. S. Public Health Service, National Institute of Health.

Postgraduate Education in Industrial Health.

WALTER L. BIERRING, M.D., Des Moines.

Commissioner, State of Iowa Department of Health.

CRYSTAL ROOM

TUESDAY MORNING, 9:30

HENRY H. KESSLER, M.D., PRESIDING

Conservation of Manpower in Connecticut.

CLIFFORD KUH, M.D., New Haven.

Chairman, Committee on Industrial Health, Connecticut State Medical Society.

Health Education for Industrial Workers.

LEVERETT D. BRISTOL, M.D., New York City.

Chairman, Committee on Education and Publications, Council on Industrial Health, American Medical Association.

LECTURE ON TRAUMATIC SURGERY WOUND HEALING

EDWARD L. HOWES, M.D., New York City.

Associate Professor of Surgery, Columbia University College of Physicians and Surgeons.

The Field of Industrial Ophthalmology.

A Report by the Committee on Industrial Ophthalmology, Section on Ophthalmology, American Medical Association.

ALBERT C. SNELL, M.D., Chairman.

ARTHUR CULLER, M.D.

HEDWIG S. KUHN, M.D.

Placement of the Worker in Industry.

JOSEPH TIFFIN, Ph.D., Lafayette, Ind.

Professor of Industrial Psychology, Purdue University.

RED LACQUER ROOM

TUESDAY AFTERNOON, 2:30

ROBERT T. LEGGE, M.D., PRESIDING

Conservation of Hearing in Industry.

C. C. BUNCH, Ph.D., Evanston, Ill.

Department of Speech Reeducation, School of Speech of Northwestern University.

Recent Trends in Physical Examinations Under Civil Service.

VERNE K. HARVEY, M.D., Washington, D. C.

Medical Director, U. S. Civil Service Commission.

Vitamin Administration in Industry

A Report Prepared by Representatives of the Council on Foods and Nutrition and the Council on Industrial Health

THE ATLANTIC CITY SESSION

Applications for Space in the Scientific Exhibit

Applications for space in the Scientific Exhibit at the Atlantic City session, both for exhibits and for motion pictures, close on January 20 Application blanks may be obtained from the section representatives or from the Director, Scientific Exhibit, American Medical Association, 535 North Dearborn Street, Chicago

FEDERAL INCOME TAX ON ACCOUNTS RECEIVABLE

PREPARED BY THE BUREAU OF LEGAL MEDICINE AND LEGISLATION

Prior to 1934, if a taxpayer died who had been on a cash receipts and disbursements basis for federal income tax purposes, the collectible accounts outstanding on his books at the time of death were not subject to income tax, and most physicians use this method in reporting their incomes for federal taxation Income tax was not paid on such accounts by any one, even though each account was collected in full after the taxpayer's death The Congress in 1934 acted to close this gap in the income tax structure by passing an amendment to the income tax act which now appears as a part of section 42 of the Internal Revenue Code

In the case of the death of a taxpayer there shall be included in computing net income for the taxable period in which falls the date of his death amounts accrued up to the date of his death if not otherwise properly includible in respect of such period or a prior period

Under this amendment, if a federal income taxpayer dies during the tax year, who has customarily executed his return on a cash receipts and disbursements basis, the return for the tax year of death must include as income not only the cash receipts but also a fair value of the outstanding accounts on the books of the taxpayer at the time of his death At the

same time that the Congress enacted this amendment it also amended section 43 relating to the period for which deductions and credits may be taken by a taxpayer by providing that—

In the case of the death of a taxpayer there shall be allowed as deductions and credits for the taxable period in which falls the date of his death, amounts accrued up to the date of his death (except deductions under section 23 (o)) if not otherwise properly allowable in respect of such period or a prior period

These two amendments were of course complementary The overall result is that, for the year of death of a taxpayer who has been on a cash receipts and disbursements basis for federal income tax purposes, outstanding accounts must be reported as income and accrued deductions and credits may be taken except deductions under section 23(o) relating to charitable and other contributions

The applicability of the amendment to section 42 to physicians was aptly illustrated in a case abstracted in THE JOURNAL on May 24, 1941, page 2426¹ In that case a physician who was engaged in the practice of medicine in a partnership died,

¹ Pfaff et al v Commissioner of Internal Revenue, 113 F (2d) 114, 61 S Ct 783

dissolving the partnership. The agreement under which the partnership operated entitled the deceased physician to share in the book accounts of the partnership to the extent of \$27,000, face value. The local collector of internal revenue determined that a fair appraisal of the decedent's interest in the partnership accounts was about one fifth of the face value and that this amount was properly includible as income for the year in which the physician died. The Supreme Court of the United States upheld the collector's determination. The interest of the physician in the outstanding accounts of the partnership was not subject to tax at its face value but on the basis of a fair appraisal of that interest. The local collector of internal revenue undoubtedly took into consideration that some of the accounts were not collectible at all and that others were collectible only in part.

While it may possibly be conceded that the situation that existed prior to 1934 with respect to the taxability of the outstanding accounts of the taxpayer at the time of his death justified remedial legislation, yet the remedy that was devised seems to be unfair to the taxpayer who has been on a cash receipts and disbursements basis. The result is that the income of the taxpayer is built up artificially for the year of death by the inclusion of uncollected accounts—accounts on which the taxpayer did not realize any income whatsoever prior to his death. The ordinary effect of the amendment to section 42 is to subject the taxpayer to higher surtax rates, with a large increase in the amount of income taxes payable for the year of death as compared with preceding years. This increase may readily impose an undue hardship on the estate of the taxpayer to provide sufficient funds to pay the tax.

Whether or not anything can be done to induce Congress to remedy the situation created by the 1934 amendment is still a question. An effort is being made, however, to obtain the enactment of corrective legislation. If section 42 could be amended to make the outstanding accounts on the books of a taxpayer at the time of his death taxable under the federal income tax law as such accounts are collected, rather than taxable as of the date of death of the taxpayer, some relief would be afforded.

Pending possible action by the Congress, several suggestions have been offered as to procedures that a physician may adopt during his lifetime to lighten the income tax load on his estate created by reason of the inclusion of the outstanding accounts as income.² Since the effect of section 42 is felt ordinarily by the estate of a physician who has been on a cash receipts and disbursements basis, consideration might be given by a physician to changing over from that basis to an accrual basis during his lifetime. The advisability of effecting such a change, however, is questionable. First, a taxpayer who has been on a cash receipts and disbursements basis cannot change over to an accrual basis without obtaining the consent of the Commissioner of Internal Revenue. Second, a taxpayer on an accrual basis must keep his books in a much more detailed manner than is otherwise required and the procedure for reporting income on that basis is complicated. Also, unless a physician who has been on a cash receipts and disbursements basis arranges to close out all of his outstanding accounts before

changing over to the accrual basis, he might be faced with the demand to pay taxes on such outstanding accounts for the year when the change-over is effective and would thus raise the same problems that now arise under section 42, on his death. Omitting from consideration, therefore, any change in the method used by a physician in reporting his income for federal income tax purposes, a physician may during his lifetime to some extent lessen the harsh effects of the amendment to section 42.

A physician should refrain from entering on his books accounts due from patients when the accounts are of doubtful collectibility or known to be uncollectible. The estate may have trouble in proving that an account is bad and in getting an allowance on it, resulting in the payment of income tax on an account which will, in fact, never be collected. A physician should write off known bad accounts at least annually. If bad accounts are carried on the books for years, the estate of the taxpayer will be subjected to the necessity of proving the uncollectibility of the accounts. Such evidence may be difficult to procure. Some physicians follow a practice of entering on their books charges for services rendered to patients who are admittedly charity cases, even though there is no intention to collect or to attempt to collect the charges. Whatever reason a physician may have for doing this, the practice will complicate the duties of the administrator or executor of the estate of the deceased physician who has followed the practice. The administrator or executor may not have any way of determining, from the books of the taxpayer, whether a particular account represents a purely charity case. This will lead to an attempt to arrive at an estimated fair value of the account for income tax purposes, despite the fact that the services were rendered with a definite understanding between the physician and the patient that they were in the category of a charity. Not only may such a practice give rise to misunderstandings between the patient and the estate, but the administrator or executor may have difficulty in convincing the collector of internal revenue of the intent of the physician to omit charge for his services even though a book entry was made indicating a charge.

It has been suggested too that a physician should keep in his files, readily available for use by his estate on his death, all procurable information which will be of aid in making a determination with respect to the collectibility or uncollectibility of an account of a particular patient. Information of this kind may be obtained from the patient or it may come to the notice of the physician from other sources. Finally, if the book accounts of the physician represent a substantial amount, he should anticipate the possibility that on his death a substantial income tax may be payable, by setting aside sufficient cash to take care of the taxes or by providing insurance to cover them. Otherwise the estate may have to be liquidated at a sacrifice to provide the necessary cash to pay the taxes. A physician will therefore do well to consult an attorney or an accountant for the purpose of estimating the amount of such taxes, so that he may make adequate provisions during his lifetime to prevent any unnecessary strain on his estate after his death.

2. Wisconsin M. J. 40: 1151 (Dec., 1941).

MEDICAL ECONOMIC ABSTRACTS

CALIFORNIA PHYSICIANS' SERVICE

Two years of experience have brought to light many unforeseen features of the California Physicians' Service. This was inevitable and expected. The board of trustees submitted a report summarizing the experiences and introducing some significant changes in the operation of the plan.¹ At the present time the plan

has thirty thousand members. Owing to its pioneer character, this plan could find no pattern on which to base its policy. An abstract of the report follows:

OUR OBJECTIVES

During these past two years we have been trying to do two things: first, to determine the possibility, the cost and the mechanics of administration of an unlimited free choice medical service plan and, second, to run a businesslike operation which would pay the doctor a reasonable fee for his service. We have accomplished the first objective, but only at some sacrifice of the second.

1. California Physicians' Service—Report to Professional Members: Announcement of Changes in Plan, California & West. Med. 55: 268 (Nov.) 1941.

Under the full coverage contract California Physicians' Service sets no maximum limit on the quantity or quality of care that the doctor may wish to extend, except the limit of one year's treatment in any single illness or injury. This contract was offered to the public as an example of what the medical profession felt that a health service plan should be. It was necessary to determine the change in the habits of people and in their attitudes toward the use of medical service when they had unlimited access thereto.

Our membership of thirty thousand is scattered throughout the state, with representation in every county. This is sufficient to give us an honest sample of experience with California medicine on a free and open access basis.

We must also devise new plans which will produce a more equitable fee for the professional services performed and which, combined with the full coverage plan, will not require a heavy contribution from the profession. This contribution will be relatively small in 1940 and 1941.

Our actual administrative expenses are well below the original maximum set for this purpose, and with increasing volume we can expect still further betterment.

FACTS ESTABLISHED

In our study of the full coverage contract and our experience thereunder, we find certain facts:

1. Our incidence of illness averages better than 17 per cent, that is, almost one fifth of our total membership is under treatment each month. This is much higher than the predictions based on any surveys or other static forms of measurement.

2. The extent of service rendered to these patients is such that, on the average, medical service costs are equal to one unit of service per dues paying member per month. An extremely large part of the services required by beneficiary members is for minor ambulatory illnesses and for chronic conditions.

3. Of the cases under treatment in a single month, nearly 40 per cent are continued from the previous month.

It is a very reasonable assumption that the high frequency of the use of the service, the high proportion of minor illnesses and the dragging on of these cases is the result largely of a complete lack of responsibility on the part of the beneficiary. He need not count cost in any fashion but merely has to present himself to the doctor and ask for whatever may be available.

4. Fifty-six per cent of our membership is composed of women, who require almost 75 per cent of the care extended.

5. Too high a percentage of all membership has been secured in the white collar classes and we have not been able to secure a sufficient percentage in the industrial groups.

These last two items confirm the necessity for our expansion into new fields in order to secure a proper balance of low income members in our service.

6. There does not seem to be any evidence of "chiseling" on the part of professional members to any significant degree. There is no excess of services in any particular district in terms of number of patients treated or in terms of quality of service rendered per patient.

POSSIBLE SOLUTIONS

With these facts in our possession we can plan for betterment. We have three possible solutions: (1) raising dues, (2) inscribing some elements of cost sharing, (3) a low cost limited plan.

Item 1 does not propose a very practical solution by itself. Raising dues would no doubt eliminate a considerable number of our present members, and such elimination would be largely

among the low income members and not among the higher income members, who have less need for the protection of the service. However, we may do something to raise the unit value without unfairly affecting the membership as a whole. Women require 20 per cent more medical care, in proportion to their number, than the men. It seems reasonable, then, that there should be an adjustment of rates for women to correct this situation.

Item 2 may be the source of considerable betterment. We propose that some responsibility shall be put on the member so that he may feel a share of the burden in direct proportion to his use of the service.

Item 3 is the most important with respect to policy and with respect to actuarial results. The high rate of dues necessary for the full coverage resulted in automatic selection of the "white collar" groups, who were the first to recognize the benefits to be secured through this service. Therefore, in order to correct this, we must now offer a low price plan that will attract the low income and industrial worker.

One of the most important factors we need to balance out the whole is volume, and volume can be secured with safety under limited plans which include only predictable and insurable factors. In this expansion we shall have the benefit of the experience of Eastern and Middle Western medical service associations. These organizations have reported fairly satisfactory experience with this type of contract. They have been able to secure very ready acceptance from the low income industrial groups of these limited service plans. If we can acquire volume under these contracts, it will put us definitely and safely into the low income field. These industrial groups have not been educated to pay for a complete medical service, but, in the experience of other medical service associations, once they have had the limited plan for a reasonable period of time they manifest interest in the broader plans.

Therefore we intend to put forth all of our effort on the acquiring of groups in the industrial field under this type of contract, limiting our acquisition activities in the full coverage plan to the two visit deductible contract only.

CHANGES MADE BY TRUSTEES

The following changes in policy were made at the meeting of the Board of Trustees on September 20:

1. A raise in the dues for women in all new groups effective Oct. 1, 1941, and raises in dues for women in existing groups according to our experience and as the contracts expire.

2. A moratorium on the sale of full coverage contracts, limiting the sale of this service to the two visit deductible contracts only (wherein the member pays the cost of the first two visits).

3. Authorization to the secretary to cancel or modify contracts with existing groups when experience indicates abuse of the service.

4. Authorization to the executive committee to develop means for the inclusion of dependents of the wage earner under the limited surgical plan.

5. Direction to the Acquisition Committee to place all its emphasis on the limited surgical contract in future acquisition.

The question naturally arises as to the over-all effect of these changes. The board of trustees feels that the modification of our full coverage contract and this expansion into new fields will result in the following:

1. We will modify our full coverage plan and we will eliminate unsatisfactory groups.

2. We will reach a new section of the population in the low income industrial groups.

3. We will balance the ideal full coverage with the business-like limited coverage.

4. We will extend our service to the industrial worker and his family, whose need for protection is much greater.

REPORT OF UNITED STATES CHILDREN'S BUREAU ADVISORY COMMITTEE MEETINGS

The Maternal and Child Health and Crippled Children's Advisory Committees of the Children's Bureau met in Washington, D. C., Dec. 1 and 2, 1941, under the chairmanship of Dr. Horton Casparis and Dr. Robin C. Buerki. The two committees met together for the first time this year and included thirty-eight physicians, four dentists, thirteen nurses, four medical social workers, one nutritionist, one physical therapist and one special educator:

Physicians

Fred L. Adair
Carl E. Badgley
S. Josephine Baker
W. W. Bauer
M. O. Bousfield
James Barrett Brown
Robin C. Buerki

Hazel C. McIntire

Many of the administrative problems of these health and medical care programs are closely related. The Divisions of Maternal and Child Health and Crippled Children of the Children's Bureau had been organized July 1, 1941 into a single Division of Health Services under the direction of Dr. Edwin F. Daily.

A progress report of the maternal and child health services throughout the country was presented by Dr. Hart E. Van Riper, assistant director for maternal and child health, Division of Health Services, and a progress report of the Crippled Children Services throughout the nation was presented by Dr. A. L. Van Horn, assistant director for crippled children, Division of Health Services. Copies of these reports may be secured from the Children's Bureau. These reports contain an analysis of state programs involving expenditures last year of \$15,664,376 under plans approved by the Children's Bureau.

The medical members of the advisory committees gave special consideration to the qualifications recommended for physicians participating in these programs. Representatives of the American Osteopathic Association were invited to advise the committees concerning the education, training and experience in pediatrics, obstetrics and orthopedics of the members of their professions. The advisory committees of the Children's Bureau after hearing these representatives recommended that the Children's Bureau make no change in its present policy of being guided by the previous recommendations of the advisory committees with respect to qualifications for physicians participating in these programs until a committee appointed by the chairman has an opportunity to study the training and qualifications of osteopathic physicians and report their findings to the Maternal and Child Health and Crippled Children's Advisory Committees of the Children's Bureau for further consideration.

Problems relating to the medical, dental, nursing, medical social and hospital services under the maternal and child health and crippled children's programs were discussed and many recommendations made for future guidance of the Children's Bureau in the administration of these programs. It was recommended that the Children's Bureau appoint a dental consultant to advise with the state agencies on the dental service in both the maternal and child health and crippled children's programs. The need for additional well trained physical therapists was discussed as it related to services for crippled children. The need for the development of child guidance services as a part of the total health program for children was discussed at some length.

Information relating to health and welfare problems of mothers and children in some of the areas most affected by defense activities was presented to the advisory committees. Methods of safeguarding the health and welfare of mothers and children in these areas were discussed and the working relationship of the Children's Bureau with the Office of Civilian Defense and with the Office of Defense, Health and Welfare Services was outlined. Dr. George Baehr, director of the medical service of the Office of Civilian Defense, described the functions of his office in helping various states and localities organize emergency medical services for civilian protection in the event of belligerent action. The work of the joint committee studying the problem of evacuation of civilians in case of need was presented by Dr. Eliot, secretary of the committee.

Major Seeley, executive officer of the Procurement and Assignment Service of the Office of Defense, Health and Welfare Service, presented a report on the development of this new service, which has been created to assist in securing physicians, dentists and veterinarians needed by the military forces and at the same time to protect the civilian population to the greatest possible extent.

The problems of providing health services in the states for minority groups and for nonresidents were outlined and recommendations made to the effect that all children irrespective of race, religion or residence should be given the same consideration.

BRITISH MEDICAL PLANNING

The conference of representatives of the Home Divisions of the British Medical Association was held in London, beginning September 11, through the following day.¹ Representatives were present from nearly all the divisions of Great Britain and northern Ireland. The question of the future organization of the medical profession seems to have dominated the discussion. One speaker spoke on "the chaotic condition of the health services of this country. There was a complete lack of coordination. Government departments vied with each other in efforts at control of various services throughout the country. The lack of order and system involved a very serious wastage of resources, both financial and administrative. Any person or corporation that could produce out of this chaos a comprehensive, well coordinated system of health services would deserve well of the country." He offered a resolution which with slight amendments was adopted and read as follows:

That in the opinion of this meeting the family and the family doctor of the patient's choice still constitute the primary essential unit in the health services of this country, and that the Medical Planning Commission be invited to regard this as a fundamental principle.

There was much discussion of the extension of medical benefit to a new insurance group and a motion was offered, which was declared out of order, that the insurance practitioners be advised not to undertake this service. A motion was carried complaining that the Insurance Acts Committee had failed to keep local committees adequately informed during the negotiations as to the changes in the insurance conditions. A resolution expressing "complete dissatisfaction with the recent action of the Insurance Acts Committee in its negotiations with the Ministry of Health" was carried by a vote of 71 to 56.

1. Conference of Representatives of Home Divisions, Brit. M. J. Supplement, Sept. 20, 1941, p. 49.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

Dr. Austin Acting State Health Officer.—Dr. Burton F. Austin, Montgomery, chief of the bureau of hygiene and nursing of the state department of health, has been appointed acting health officer of Alabama, pending a permanent selection to succeed the late Dr. James N. Baker, Montgomery.

CALIFORNIA

Society News.—Dr. William Edward Chamberlain, Philadelphia, addressed the San Francisco County Medical Society, December 2, on "Role of Fluoroscopy in Medicine."—The Los Angeles Society of Neurology and Psychiatry was addressed, December 17, by Drs. William T. Grant and Leo J. Adelstein on "Quantitative Methods in Neurologic Diagnosis" and "Surgical Treatment of Syringobulbia," respectively. Both are from Los Angeles.

Laboratory for Research in Ophthalmology.—The University of California recently opened a new laboratory to be used for pathology and research in ophthalmology, to be jointly directed by the division of ophthalmology in conjunction with the divisions of ophthalmology and pathology. Dr. Michael J. Hogan, San Francisco, has been made director of the new unit. The laboratory was made possible by a fund of \$70,000 known as the Charles Taylor Reeves Foundation, the income from which is to be used in the study of diseases of the eye. Actual construction was accomplished through a donation of Mrs. E. S. Heller.

CONNECTICUT

Changes in Health Officers.—Dr. Thomas J. Bergin, Cos Cob, has been appointed full time health officer of the town of Greenwich.—Dr. Albert E. Childs, Litchfield, has succeeded Elton R. Skilton, as health officer of Morris.—Dr. Philip E. Schwartz has been appointed health officer of Portland, succeeding Dr. John R. Tarrant.—Dr. Ernest R. Pendleton has been appointed health officer of East Granby and Hartland, succeeding, respectively, Adolph Viets and Edward A. Gaylord.

DISTRICT OF COLUMBIA

Course in Aviation Ophthalmology and Medicine.—The George Washington University School of Medicine, Washington, announces a postgraduate course in aviation ophthalmology and aviation medicine, February 5-7. A course in ophthalmology will be held, February 2-4. In the course covering aviation the guest lecturers will be:

Dr. David N. W. Grant, lieutenant colonel, M. C., U. S. Army.
Dr. Frederic H. Thorne, lieutenant colonel, M. C., U. S. Army.
Dr. John M. Hargreaves, major, M. C., U. S. Army.
Dr. Major S. White, major, M. C., U. S. Army.
Dr. John C. Adams, captain, M. C., U. S. Navy.
Dr. Eric Liljencrantz, commander, M. C., U. S. N. R.
Dr. Leon D. Carson, lieutenant commander, M. C., U. S. Navy, Washington, D. C.
Dr. Arnold D. Tuttle, medical director, United Air Lines, Chicago.
Dr. William Hodges McKnight, medical director of American Air Lines, Fort Worth, Texas.
Dr. William Randolph Lovelace II, division of surgery, Mayo Clinic, Rochester, Minn.
Ross A. McFarland, Ph.D., Boston, lieutenant commander, A.-V. (S.) U. S. N. R.

A postgraduate course in ophthalmology will be held, February 2-4. Participating will be Drs. Samuel Hanford McKee, Montreal, Que.; William L. Benedict, Rochester, Minn.; Edwin B. Dunphy, Boston; Harry S. Gradle, Chicago; Meyer Wiener, St. Louis; Algernon B. Reese, New York; Ernest A. W. Sheppard, Washington, D. C.; Avery DeH. Prangen, Rochester, Minn.; William Thornwall Davis, Washington, and Walter I. Lillie, Philadelphia. A course in ocular surgery, pathology and orthoptics is announced for January 26-31. On February 2 the speakers at a meeting of the Washington Ophthalmological

Society will be Dr. McKee, on "Routine Examination of the Fundus in Diabetes"; Dr. Reese, "Exophthalmos Associated with Thyroid Disease," and Dr. Wiener, "Reflections on Glaucoma Surgery After Forty Years' Experience."

Society News.—Dr. Herrman L. Blumgart, Boston, discussed "Varieties of Cardiac Pain, Their Clinical and Pathologic Significance," before the Washington Heart Association, November 26.—At a meeting of the Washington Ophthalmological Society, November 3, Dr. Thomas H. Johnson, New York, spoke on neuro-ophthalmology.—Dr. John M. Converse, New York, addressed a meeting of the medical and dental officers of the navy on duty in the District of Columbia and vicinity at the Naval Medical School, December 1, on "Wartime Surgery in England."—The Medical Society of the District of Columbia will devote its meeting, January 21, to a panel discussion on peripheral vascular diseases with Dr. Wallace M. Yater as the moderator. Others participating will include Drs. Norman E. Freeman, Philadelphia; Abram Wilbur Duryee, New York, and James Ross Veal, Washington.

ILLINOIS

Changes in Hospital Superintendents.—Dr. Joseph S. Drabanski has been appointed managing officer of the Chicago State Hospital, succeeding Dr. Edward F. Dombrowski. Dr. John B. Cipriani, Chicago, has been named managing officer of the Illinois Eye and Ear Infirmary, succeeding Dr. Stanley W. Parowski. Dr. James L. Smith, Chicago, became managing officer of the Jacksonville State Hospital on December 1.

Chicago

Course in Electrocardiographic Interpretation.—A course in electrocardiographic interpretation for graduate physicians will be given at Michael Reese Hospital by Dr. Louis N. Katz, director of cardiovascular research. The class will meet each week, starting Wednesday February 18, for twelve weeks, from 7 to 9 p. m. Additional information may be obtained from the Cardiovascular Department, Michael Reese Hospital.

Chicago Tumor Institute Buys Home.—The Chicago Tumor Institute, 21 West Elm Street, announces the purchase of the property where it has been situated since its establishment in 1938. Previously the clinic leased the property. More than 2,000 persons have been treated at the clinic since it opened; one third of the patients were treated free and one third at reduced rates.

Tons of Dust Fall Annually on Chicago.—The smoke abatement department has reported that a monthly average of 55.2 tons of dust per square mile fell last year in Chicago as compared with 54.1 tons in 1940. The downfall of dust at twenty-two stations throughout the city is the measuring stick used to determine the average. May was the dustiest month with 84.3 tons per square mile, compared with 59.6 in the same month in 1940. Increased industrial activity was said to be responsible for much of the 1941 gain. It was also stated that defense activity had forced many Chicago firms to use cheaper grades of coal, which make more smoke unless fired properly. The station located on the top of the building at 33 North La Salle Street, one of two stations down town, had the greatest dust fall, averaging 134.9 tons per square mile monthly. Among the outlying stations the one at 3532 Sheffield Avenue had the highest average with 81.7 tons of dust per square mile monthly. The cleanest outside station, according to the report, was at 1620 West Ninety-Ninth Street with a dust fall of 32.8 tons per square mile monthly.

INDIANA

Appointments to State Board of Health.—Drs. Herman M. Baker, Evansville, and Henry C. Metcalf, Connersville, were recently appointed to the state board of health to succeed Dr. John C. Glackman, Rockport, who resigned several months ago, and Dr. William Wise, Indianapolis. Drs. Ernest Rupel, Indianapolis, and Edmund M. Van Buskirk, Fort Wayne, were reappointed to the board. This is the first time in several months that the board has had a full membership, it is reported.

KANSAS

Health Service Director Goes to Milwaukee.—Dr. Richard F. Boyd, Topeka, who has been director of local health services of the Kansas State Board of Health, recently resigned to become regional medical officer for the Farm Security Administration in Michigan, Wisconsin and Minnesota. He will reside in Milwaukee.

Menninger Foundation Organized.—Announcement is made of the incorporation under the laws of Kansas of the Menninger Foundation, with headquarters in Topeka. The new foundation aims to provide psychiatric education, especially the training of young physicians in psychiatry, to encourage research in psychiatric and psychologic fields; to make available psychiatric treatment for patients in the low income bracket and to prevent mental illness, especially through development of child psychiatry and the application of psychiatric knowledge to education and child rearing. Officers of the foundation are Dr. Karl A. Menninger, president; Mr. John R. Stone, vice president; Dr. William C. Menninger, secretary, and Dr. Robert P. Knight, Topeka, treasurer, and trustees are:

Dr. Winfred Overholser, medical superintendent, St. Elizabeths Hospital, Washington, D. C.

Mrs. Albert Lasker, New York and Chicago.

Dr. John C. Whitehorn, Baltimore.

Mrs. Lucy Stearns McLaughlin, Santa Fe, N. M.

Dr. James Roscoe Miller, Chicago.

Mrs. Sidney C. Borg, New York.

George W. Hite Jr., New York.

Grants have been made for a ten year study of the place of occupational therapy in psychiatric treatment, for a seminar and special Bulletin on *Military Psychiatry and the distribution of this information to physicians on the medical advisory boards of the country, and for research in the use of hypnosis in emergency psychotherapy and in substantiating newer psychiatric theories.*

KENTUCKY

Changes in Health Officers.—Dr. Jesse M. Dishman, Princeton, health officer of Caldwell County, has been appointed health officer of Fulton County, succeeding Dr. Layson B. Swann, Paducah, who resigned to enter the army.—Dr. Frank L. Lapsley, Shelbyville, has been reelected health officer of Shelby County for a four year term.

Society News.—The Jefferson County Medical Society devoted its meeting in Louisville, December 15, to a symposium on fractures; the speakers were Drs. William Barnett Owen, William McDaniel Ewing, Harry Goldberg, Orville Ray Miller and Robertson O. Joplin, Louisville, and E. C. Hume, D.D.S.—At a meeting of the Louisville Medico-Chirurgical Society on December 12 Dr. Michael J. Henry discussed "Primary Carcinoma of the Liver" and Dr. Laman A. Gray presented a case report on "Extensive Pelvic Endometriosis." Both are of Louisville.

MICHIGAN

State Council of Health.—The governor recently appointed Drs. Harold E. Wisner, Detroit, a member of the state council of health to succeed Dr. Addison D. Aldrich, Houghton; Dr. Oscar D. Stryker, Fremont, was also appointed a member. Dr. Roy C. Perkins, Bay City, was reappointed to the council. Other members are Henry F. Vaughan, Dr. P.H., Ann Arbor, and John A. Galbo, D.D.S., Detroit.

MINNESOTA

Personal.—Dr. Frank J. Hirschboeck, Duluth, has been appointed by the governor a member of the state teachers' college board.—Dr. Cyril M. Smith, Duluth, has been appointed a member of the Minnesota Boxing Commission, his term to run until January 1943.—Dr. Reino H. Puumala, Cloquet, has been named coroner for Carlton County, succeeding the late Dr. Franklin W. S. Raiter, Cloquet, who had served in the position for twenty-five years.—John E. Anderson, Ph.D., director of the child welfare institute, University of Minnesota, Minneapolis, has been appointed chairman of the Minnesota committee of the White House Conference on Children in a Democracy. Dr. Roger L. J. Kennedy, Rochester, has been named a member.

Award First Certificate in Tuberculosis Control Program.—At a ceremony in the Tyler High School Auditorium, Tyler, Dr. Berton J. Branton, Willmar, president of the Minnesota State Medical Association, presented a certificate of accreditation signed by Governor Stassen to M. L. Anderson, Canby, chairman of the board of county commissioners, who accepted it for Lincoln County. The certificate was the first awarded in the cooperative program of the state association and the state department of health to accredit counties showing a tuberculosis mortality rate not to exceed 10 per hundred thousand of population and an incidence of tuberculous infection among seniors in high school not to exceed 15 per cent. The mortality rate must be based on a five year average and the student rate on tests of at least 80 per cent of the senior stu-

dents of the county. The program is believed to be the first adopted for tuberculosis control in a human population and is patterned after the federal plan to accredit areas showing eradication of tuberculosis in cattle.

MISSISSIPPI

Personal.—Dr. Bert R. Burgoyne, Lake Providence, La., has been appointed superintendent of the South Mississippi Charity Hospital, Laurel, succeeding Dr. John C. Butler, Laurel, who resigned to devote his full time to private practice.—Dr. Harold H. Rutledge, Richmond, Ky., has been chosen director of the Tate County Health Department.

Society News.—The Delta Medical Society was addressed at its thirty-eighth semiannual meeting at the Hotel Greenville recently in Greenville by Drs. Howard A. Nelson, Greenwood, on "The Patient—His Personality and His Disease"; Otis H. Beck, Greenville, "Urethral Strictures"; Toxey E. Hall, Belzoni, "Subdural Hematoma"; Lawrence L. Beall, Cleveland, "Treatment of Facial Injuries," and Bernard H. Booth, Drew, "Malaria." Dr. Grady W. Reagan, Little Rock, Ark., was the guest speaker, and his subject was "The Medical Treatment of Kidney Infection."

MISSOURI

Dr. Graham Chosen for Lister Lectures.—Dr. Evarts A. Graham, Bixby professor of surgery, Washington University School of Medicine, St. Louis, has been awarded the Lister Medal for 1942, which is given in recognition of distinguished contributions to surgical science, according to *Science*. He will deliver the Lister Memorial Lectures during 1942 or later under the auspices of the Royal College of Surgeons of England.

Society News.—Dr. Albert C. Furstenberg, Ann Arbor, Mich., discussed "Medical Treatment of Ménière's Disease" before the St. Louis Medical Society on November 25. Dr. William Boyd, professor of pathology and bacteriology, University of Toronto Faculty of Medicine, Toronto, spoke before the society, December 2, on "Cause and Effect in Relation to Disease." Dr. James C. Sargent, Milwaukee, lectured before the society on December 16 under the auspices of the St. Louis Urological Society; his subject was "Common Injuries Involving the Urinary Tract."

NEBRASKA

Officers of State Medical Board.—The Nebraska State Board of Examiners in Medicine was reorganized at a meeting, December 10. The following officers were elected: Drs. William R. Boyer, Pawnee City, president; Ernest T. Manning, Omaha, vice president, and Henry J. Lehnhoff, Lincoln.

NEW YORK

New Professor of Anesthesia.—Dr. Paul W. Searles, associate in anesthesia, University of Buffalo School of Medicine, Buffalo, and chief anesthetist in the General Hospital, has been appointed professor of anesthesia and head of the department. He succeeds Dr. John H. Evans, who was elected professor emeritus. Dr. Searles graduated at the University of Minnesota Medical School, Minneapolis, in 1934.

Cancer Institute.—A regional cancer institute will be conducted in Syracuse on January 17 under the auspices of the state medical society, Tumor Clinic Association of the State of New York, Syracuse University College of Medicine and the division of cancer control of the state department of health. Dr. Herman G. Weiskotten, dean of the school of medicine, will open the program, which has been designated a "symposium for practitioners." The speakers will be:

Dr. Bowman C. Crowell, Chicago, Role of the Cancer Clinic in Cancer Control.

Dr. Lloyd F. Craver, New York, The General Practitioner and the Diagnosis of Cancer.

Dr. John J. Morton Jr., Rochester, Advance in Surgical Treatment of Cancer.

Dr. John Howard Ferguson, Syracuse, Biopsy—Indications and Methods.

The evening program will be opened by Dr. Edward S. Godfrey Jr., Albany, state health commissioner; Drs. Guilford Allen Robinson, New York, and Walter T. Murphy, Buffalo, will discuss "Principles of Radium and X-Ray Therapy," and Byrl R. Kirklin, Rochester, Minn., "X-Ray as a Diagnostic Aid in Cancer."

Study of Family Care.—Dr. Frank F. Tallman, clinical director of the Rockland State Hospital, Orangeburg, has been appointed director of the study of parole and family care by the temporary commission on state hospital problems. Central

Islip (N. Y.) State Hospital with an urban population and the Marcy State Hospital, Oneida County, with patients from rural areas were selected for the study, the object of which is to determine to what extent additional psychiatric social work results in increasing paroles and family care. One physician and three social workers have been assigned to Central Islip and one physician and two social workers to Marcy, releasing personnel which can give full time to the study. Dr. Tallman has been granted a leave of absence from the Rockland hospital to devote full time to the work.

New York City

Hospital News.—The City Hospital announced a special lecture to its chest clinic by Dr. Edward D. Churchill, John Homans professor of surgery, Harvard Medical School, Boston, November 12, on "Primary Carcinoma of the Lung."

The Harvey Lecture.—Dr. William C. Stadie, associate professor of research medicine, University of Pennsylvania School of Medicine, will deliver the fourth Harvey Society Lecture of the current series at the New York Academy of Medicine, January 15. His subject will be "Intermediary Metabolism in Diabetes Mellitus."

Dr. Hecht Awarded Medal.—The Frederic Ives Medal of the Optical Society of America was presented on October 24 to Selig Hecht, Ph.D., professor of biophysics at Columbia University, in recognition of "distinguished work in the field of optics." *Science* reports. Kasson S. Gibson, Ph.D., Washington, D. C., president of the society, presented the medal to Dr. Hecht during the twenty-sixth annual meeting of the society in New York. The medal was established in 1928 by Herbert E. Ives, Ph.D., Montclair, N. J., of the Bell Telephone Laboratories, in memory of his father.

Fellowships for Women Physicians.—The Women's Medical Association of the City of New York offers a Mary Putnam Jacobi Fellowship for medical research of \$1,000. Available Oct. 1, 1942, the fellowship is open to any woman doctor, either American or foreign, who is a graduate of a reputable medical school. Applications must be filed by March 1 and must be accompanied by statements by persons other than the candidate as to health, educational qualifications and previous work. The applicant should state the problem she proposes to investigate and send her photograph. The recipient of the fellowship will be expected to give full time to her study and make a report for publication on its completion. Application blanks may be obtained from the Mary Putnam Jacobi Fellowship Committee of the association, 321 East Fiftyfifth Street.

Personal.—Dr. Jacob B. Prager has been appointed medical director of the Israel-Zion Hospital, Brooklyn.—Dr. Jacob M. Gerslberg, president of the International and Spanish Speaking Association of Physicians, Dentists and Pharmacists, recently returned from a trip to Mexico and various parts of the United States. He formed new chapters of the international association in Chandler and Phoenix, Ariz., San Diego, Calif., and El Paso and San Antonio, Texas.—The Medical Society of the County of Kings will receive \$1,000 and the medical library of the late Dr. Henry Joachim in accordance with a stipulation in his will.—Dr. Thomas A. McGoldrick, Brooklyn, has been appointed chief of the emergency medical service under the U. S. Civilian Defense.—Dr. Joseph Francis McCarthy, professor of urology at the New York Polyclinic Medical School and Hospital, was honored recently when a new wing at the Barros Luco Hospital, Santiago, Chile, was named for him.—The medical and nonmedical staff of Manhattan State Hospital, Wards Island, held a reception there December 8 for Dr. John R. Knapp, chief psychiatrist, who has retired after more than forty-five years' service; recently he has been temporarily serving as acting superintendent. Dr. Knapp was presented with a watch and traveling bag.

Medical Aid for Dependent Children.—Families qualified for aid to dependent children have been included under the medical and nursing service which previously has been available to families on home relief, to veterans and to the blind and aged, according to the *New York Times*. The extension of the service was one of the promised benefits of the merger last July of the board of child welfare with the welfare department of the city. About five thousand physicians representing the medical societies of the city will constitute the panel approved by the medical advisory committee of the welfare department, which is circulating physicians to learn how many wish to respond to aid to dependent children calls. On Novem-

ber 16 about three thousand six hundred had responded affirmatively. They will be paid \$2 a visit. There will be fifteen hundred approved pharmacists to whom patients may go for medicine. Bills for medicines will be paid by the welfare department. The number of families classified under aid to dependent children is 22,140; the number of children is 40,690, and the total eligible for the service is about 62,000, it was stated. In ease of the aged, the blind and dependent children, the welfare department will be unable to pay attending physicians directly as it does in the case of home relief families. The Social Security Act forbids specific payments and requires that checks be sent to the clients, who cannot be compelled to turn over the cash to the physician. As a result the beneficiaries often do not pay the physician, who in turn has no claim against the welfare department. William Hodson, welfare commissioner, said the Social Security Board was trying to have the law amended.

NORTH CAROLINA

Lectures on Medical History.—Dr. William G. Harrison, Birmingham, Ala., gave a series of public lectures on the history of medicine at the Bowman Gray School of Medicine, Winston-Salem, November 24-28. His topics were "Animal Medicine," "Folklore in Medicine," "The Dawn of Medicine in the East," "Early Greek Medicine" and "Classical Greek Medicine."

Personal.—Dr. Thomas O. Coppedge, Nashville, is now health officer of Nash County.—Dr. Leo B. Skeen, Sanatorium, has been named health officer of Iredell County.—Dr. Vernon W. Taylor Jr., Madison, has been appointed assistant medical director of the city hospital system of Winston-Salem, a position recently created because of an expanded program of public service.

Hospital for Ashe County.—The new twenty-four bed Ashe County Memorial Hospital, Jefferson, was dedicated and formally opened, November 2. The two story stone structure is a WPA project and cost \$60,000. Speakers at the dedication included Hon. Frank Dryden, Washington, D. C., acting WPA commissioner; Congressman Robert L. Doughton, Laurel Springs, and Dr. Watson S. Rankin, Charlotte.

NORTH DAKOTA

Sanatorium Superintendent Goes to Seattle.—Dr. Cedric Northrop, superintendent of the state tuberculosis sanatorium at San Haven, has resigned, effective December 1. He plans to accept a position as director of tuberculosis control in the Washington State Department of Health, Seattle, according to the *Journal-Lancet*.

OHIO

Employees Eligible for Retirement to be Examined.—Three physicians were named to a new board to examine city employees of Toledo who have reached the retirement age of 70 but who want their services retained, newspapers reported on December 2. The city council authorized the appointment of the board members on the recommendation of the Academy of Medicine of Toledo and Lucas County. The physicians are Drs. William Frank Maxwell, Claude E. Price and William G. Gardiner. The state legislature ruled some time ago that all employees 70 or older must retire this year. It recently advanced the deadline to the end of 1945 if employees 70 or past can qualify physically to continue working.

Cleveland Health Museum Observes Anniversary.—The Cleveland Museum of Health and Hygiene marked its first anniversary, November 14, at a luncheon held in cooperation with the chamber of commerce. Dr. Victor G. Heiser, New York, spoke on "Toughen Up, America." During the year, thirty-seven thousand persons from forty-four states visited the museum and two hundred and eighty-nine guided tours were conducted through the museum by its staff and volunteer guides from the woman's auxiliary of the Academy of Medicine of Cleveland. The museum has eight hundred and eight members and contributors and is maintained by them and by private subscriptions. Beginning this month the museum will offer three to six month internships in health education; selected applicants will learn how to design, build and install exhibits that effectively teach functions of the body. Dr. Bruno Gebhard, former curator of the Dresden Hygiene Museum, is director of the museum, which was developed as a clearing house for popular health information under the direction of the Academy of Medicine of Cleveland.

OKLAHOMA

Society News.—The Pottawatomie County Medical Society was addressed recently by Dr. William M. Gallaher on "Furuncle of the Nose" and Dr. James M. Byrum, "Some Observations in Obstetrical Surgery." Both are of Shawnee.

Benevolent Fund Committee Named.—The Oklahoma State Medical Association has appointed a special committee to report on the handling of the association's surplus fund for benevolent and other purposes. Members are Drs. Galvin L. Johnson, chairman, Pauls Valley; Robert U. Patterson, dean, University of Oklahoma School of Medicine, Oklahoma City, and George R. Osborn, Tulsa.

Committee to Consider Control of Certain Drugs.—The state medical association has appointed a committee to confer with a committee of the Oklahoma Pharmaceutical Association about regulating the sale of certain drugs which may be a menace to health when used by the public without proper prescriptions. Members of the medical association's committee are Drs. Grady F. Mathews, Oklahoma City, chairman; William Turner Bynum, Chickasha, and Leo J. Starry, Oklahoma City.

Dermatologists Entertain Texas Group.—The Texas Dermatological Association was the guest recently of the Oklahoma Dermatological Association at a meeting at the University Hospital, Oklahoma City. Twenty-two cases for diagnosis and study were presented by Drs. Onis G. Hazel and John H. Lamb, both of Oklahoma City. The group was entertained at a barbecue supper at the country cabin of Dr. Everett S. Lain, Oklahoma City. The Texas association plans to reciprocate at its fall meeting in 1942.

OREGON

Mosquito Eradication Program.—The Works Progress Administration has allocated \$131,200 to the state board of health to eradicate mosquitoes in areas adjacent to defense industries and military and naval establishments.

Course in Pediatrics.—The University of Oregon Medical School, Portland, conducted a postgraduate course in pediatrics, December 29-31, for physicians of Oregon and Washington, under the direction of the school's department of pediatrics in cooperation with the divisions of maternal and child health of Oregon and Washington state boards of health. Speakers included Drs. Joseph B. Bilderback, Morris L. Bridgeman, James W. Rosenfeld, Paul V. Woolley Jr., Scott H. Goodnight, Adolph Weinzi, John A. Gius and Charles E. Gurney.

PENNSYLVANIA

Society News.—The Mercer County Medical Society was addressed in Sharon recently by Dr. John B. Price, Norristown, and John H. Brownback, A.B., professor of biology at Ursinus College, Collegeville, on "Relationship of the Autonomic Nervous System to Upper Respiratory Symptoms" and "Embryology of the Autonomic Nervous System" respectively. —Dr. Joseph H. Barach, Pittsburgh, addressed the Westmoreland County Medical Society, December 2, on "Diabetes and Its Complications."

Philadelphia

Personal.—Dr. Hubley R. Owen resigned as chairman of the council of defense to give full time to his work as director of public health, effective January 1. Dr. Owen had been serving as defense chairman since last May.

New Chair in Hematology.—The Thomas Drake Martinez Cardeza chair of clinical medicine and hematology has been established at Jefferson Medical College with Dr. Harold Walter Jones, associate professor of medicine at the school, as the first incumbent. The funds were provided by Thomas Drake Martinez Cardeza to carry on the work of the Charlotte Drake Cardeza Foundation for the study and investigation of diseases of the blood and allied conditions. Mr. and Mrs. Cardeza established the foundation in 1938 and have since maintained it in memory of the former's mother. Dr. Jones will continue teaching in the medical college and direct all activities of the foundation. He graduated at Jefferson in 1917.

RHODE ISLAND

Society News.—Dr. James P. Deery, Providence, discussed "Tuberculosis Case Finding at the Army Induction Station" before the Providence Medical Association, December 1, and Dr. Channing C. Simmons, Boston, "Diagnosis of Bone Tumors."

Advisory Council of Health.—Governor McGrath recently appointed Dr. Charles F. Gormly, a vice president of the state medical society, and Mr. John E. Farrell, executive secretary of the Providence Medical Association, as members of the advisory council to the state department of health. Other members of the council are Miss Winifred L. Fitzpatrick, R.N.; Mr. Kenneth D. MacColl, and Dr. Dennett L. Richardson, medical superintendent of the Rhode Island Hospital. All are of Providence.

SOUTH CAROLINA

Clinic Named in Honor of Mill Physician.—The Wood Memorial Clinic was opened in November at the Slater Mill in upper Greenville County. The clinic has been dedicated to the service of the eight hundred families of the textile community and named in honor of the late Dr. Landrum W. Wood, Slater, who for years served there. The unit has an operating room for minor surgical work, dental surgery room, diet kitchen and laboratory. Two beds for convalescence and diagnosis will be added later as the need may arise, newspapers reported.

TEXAS

Personal.—Dr. Jack R. Ewalt, assistant professor of psychiatry at the University of Colorado School of Medicine, Denver, has been named associate professor of neuropsychiatry at the University of Texas School of Medicine, Galveston. —Dr. Horace A. Baker, Wills Point, has been appointed health officer of Van Zandt County.

Society News.—Dr. Charles H. Warren, among others, addressed the Dallas County Medical Society in Dallas, October 23, on "Sulfanilamide as Prophylaxis in Contaminated Traumatic Wound Cases." —The Texas Pediatric Society held its annual meeting recently in Dallas; officers are Drs. Percy E. Luecke, Dallas, president; Frank H. Lancaster, Houston, president-elect, and John E. Ashby, Dallas, secretary-treasurer. The society will meet in San Antonio in October 1942.

WISCONSIN

District Meeting.—At a meeting of the Ninth Council District Medical Society in Wausau, November 13, Drs. Alexander E. Brown, Rochester, spoke on "The Present Day Status of the Sulfonamide Compounds" and Ernest M. Hammes, St. Paul, "Diagnosis and Treatment of Injuries and Diseases of the Spinal Cord."

Dr. Seeger Goes to Texas.—Dr. Stanley J. Seeger, chief of staff of the Milwaukee Children's Hospital and chief of staff of Columbia Hospital, has taken up his residence in Texarkana, Texas. Dr. Seeger has been chairman of the Council on Industrial Health of the American Medical Association since its organization in 1937; he was president of the Medical Society of Milwaukee County in 1926 and of the state medical society in 1933-1934. Texarkana is Mrs. Seeger's former home.

Personal.—Dr. George M. Shinnors, Green Bay, has been appointed health commissioner of Green Bay. —Dr. Charles D. Boyd, Kaukauna, was guest of honor at a banquet recently, marking his completion of fifty years' practice in the community. —Dr. Elmer L. Sevringhaus, Madison, has been elected an honorary foreign member of the National Academy of Medicine of Buenos Aires. Dr. Sevringhaus toured South America early this year under a government travel grant. —Dr. Willard M. Sonnenburg, Sheboygan, was recently elected president of the Sheboygan County Conservation Alliance.

GENERAL

Another Fraudulent Solicitor.—The National Publishers Association, New York, announces that a fraudulent magazine solicitor using the names J. R. Hamilton, J. S. Stewart and C. O. Reed has been calling on physicians exclusively, offering subscriptions to *Newsweek* featuring a "special publicity offer —40 issues *Newsweek*." This man issues a green store receipt bearing the offer in a rubber-stamp imprint and also rubber-stamps "Newsweek, 152 West 42nd St., New York City." He pockets full amount of his collections, making no report of the orders. Physicians approached by this solicitor are urged to notify the police and ask them to wire the National Publishers Association, 232 Madison Avenue, New York, collect. The fraudulent representative's description is: age 40 years, height 5 feet 10 inches, weight about 175 pounds; he has brown eyes and black hair.

National Academy of Sciences Closes Building to Public.—Because of the large amount of work being done by the National Academy of Sciences and National Research Council committees in an advisory capacity to the government during the present emergency, and because exhibit and other rooms formerly open to the public are now occupied as offices, the Council of the National Academy of Sciences has directed the National Academy of Sciences Building be closed to the public until further notice. The academy regrets that this step is necessary but will, as soon as circumstances permit, reinstall exhibits of scientific interest to the public. The annual meeting of the academy will be held in the academy building, April 27-29, but attendance, formerly open to the public, will be limited to academy members, their invited guests, the press and to nonmembers who present papers before the academy. Only members of the academy and of the press will receive abstracts of papers.

Extensive Survey of Eye Injuries in Industry.—A report has just been issued of a study of eye injuries in industry which was sponsored by the National Society for the Prevention of Blindness. The report, prepared by the late Louis Resnick, industrial relations director of the society, is based on two decades of personal observations in workshops throughout the country and contains a complete summary of eye hazards existing in American industry today. According to the study, about three hundred thousand eye injuries occur in factories, mills, mines and workshops each year. Of the thousand eye injuries expected to occur each day, all but twenty could be prevented, it was said. There are in the United States more than eighty thousand persons who have lost the sight of one eye as a result of industrial hazards and close to eight thousand who have lost the sight of both eyes; the number of persons who have lost permanently part of the vision of one or both eyes undoubtedly runs into hundreds of thousands. These are conservative estimates and since many factors are involved in accurate reporting, the survey points out that the injuries considered represent only a part of the total number which actually occur. Eye injuries lead to the loss of more than fifty-three million man hours of work yearly, the report states. Discussing the compensation for such injuries, the report shows that in liberal states the maximum compensation paid for total loss of vision is two thirds of the wage received by the injured workman at the time of the accident, whereas in some states, as in Oregon, the maximum compensation for total loss of vision is as low as \$30 a month for life. Great financial loss to the workman and the employer could be averted by the cooperation of the two groups in the utilization of demonstrated methods of preventing accidents and diseases.

HAWAII

Dr. Wayson Completes Fifty Years in Medicine.—Dr. James T. Wayson, who from 1918 to 1931 was general health officer of the Territory of Hawaii, Honolulu, recently completed fifty years in the practice of medicine. A few years after his graduation at the University of California Medical School, San Francisco, Dr. Wayson went to Hawaii, where he was at one time physician in charge of the Kalihi Boys' Home and superintendent of the Kapiolani Girls' Home, Honolulu. He was city and county physician of Honolulu from 1911 to 1918. Since 1932 he has been physician to the Board of Leper Hospitals. He has served as a member of the territorial board of health and of the board of medical examiners for several terms. Dr. Wayson, a native of Port Townsend, Wash., is 71 years of age.

CORRECTIONS

Transfusion of Blood and Blood Substitutes.—In an editorial under this title in *THE JOURNAL*, Nov. 8, 1941, page 1627, in the last paragraph seven lines from the end is the statement "One thousand cc. of plasma gives 8 cc. of dried product." This should have read "One hundred cc. of plasma gives 8 cc. of dried product."

Sodium Lactate in Distilled Water.—In the clinical note by Quick and Lord entitled "Acute Hemolytic Anemia Following Sulfathiazole Administration" in *THE JOURNAL*, Nov. 15, 1941, page 1704, the authors state that they used "infusions of sodium lactate—Ringer's solution." This was an error and should have been "infusion of sodium lactate in distilled water."

Government Services

Committee for Vocational Rehabilitation

A special committee representing federal agencies concerned with the vocational rehabilitation of war veterans and civilians was appointed on Dec. 22, 1941, by Paul V. McNutt, federal security administrator, according to the *New York Times*. It is planned to draft a program of rehabilitation to meet the current and postwar suffering. The committee membership includes Watson Miller, assistant federal security administrator, chairman, and representatives of the Office of Production Management, the Social Security Board, the Veterans Administration, the Public Health Service, the Employees Compensation Commission, the Department of Labor and the Office of Education. The *Times* reported that both organized labor and industrial management are to be approached for advice and cooperation.

Hoff Hall at Army Field Service School

Hoff Hall, the new academic building of the Medical Field Service School at Carlisle Barracks, Pa., was formally accepted by the acting commandant of the school on November 12. It is a two and one-half story stone structure costing \$350,000. The building contains an auditorium with seating capacity for four hundred persons and facilities for sound pictures and for instructional aid. There are two classrooms each with a capacity for four hundred persons and an air conditioned library. In addition there are smaller classrooms, offices, and a museum.

Hoff Hall.

Hoff Hall is built of native limestone quarried partly on the military reservation and is faced with Vermont granite. It is named for the late Col. John Van Rensselaer Hoff, a distinguished officer of the medical corps and leader in the movement by which the medical department became a staff corps. He graduated at Albany (N. Y.) Medical College in 1871 and at the College of Physicians and Surgeons in the City of New York in 1874. In the same year he was appointed first lieutenant and assistant surgeon, U. S. Army. He organized the first detachment of the hospital corps in the army at Fort Reno, Indian Territory, and the first company of instruction hospital corps at Fort Riley, Kan., in 1891. He was recommended for a medal of honor in the Sioux campaign in 1890 and 1891. He served through the war with Spain as chief surgeon in Puerto Rico, was chief surgeon of the China relief expedition in 1900 and was a member of the faculty of the Army Medical School in 1901 and 1902. In 1905 he was commissioned assistant surgeon general and in that year was detailed observer with the Russian army in the Russo-Japanese War; from 1910 until retirement for age in 1912 he was chief surgeon of the Department of the East. Colonel Hoff was a pioneer in the training of enlisted men of the medical department. He insisted that the medical soldier is as much a soldier as any other and must receive adequate drill, and training. His ideas have prevailed. At the recent exercises Col. Edgar E. Hume, acting commandant, received the key to the building from the constructing quartermaster, Lieut. Col. Jacob Osterman.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Nov. 22, 1941.

Food in Case of Invasion and Heavy Bombing

The minister of food has announced plans to secure an orderly distribution of food in the event of invasion. In threatened districts food shops would be closed—probably for a few hours—to permit rapid stock taking so that the voluntary food officers would know precisely what food was available and be in a position, with the help of military advice, to decide what amounts would be distributed to each person. Reserves of food in bulk belonging to the ministry vary from district to district, according to military advice. Householders are told that the quantity of food stored for an emergency should be one week's or at most two weeks' supply. Plans for emergency feeding on a wide scale in London have been made by the county council in case heavy bombing of the capital is resumed. Catering establishments of all kinds—hotels and workmen's dining rooms, clubs, teashops, taverns and milk bars—have all been brought in and, where practicable, industrial canteens also will assist. These plans will be put into force only when the authorities consider the emergency to be really grave and only in those parts of the capital where damage to buildings, gas, electricity, water and transport services make emergency feeding essential. Given such conditions, three hundred voluntary officials stand ready to organize a meals service for any emergency. Standard menus will be arranged. Tea will be available at 2 cents a cup, milk at 4 cents a glass, soup (pea or vegetable) at 4 cents a mug, rice pudding for children under 5 at 5 cents a plate, milk soup with bread for children under 5 at 12 cents a mug, meat and vegetable stew with bread 12 cents a plate, meat and vegetables at 18 cents. People will be asked to take with them to these feeding centers their own dishes and cutlery and will be told that basins and mugs are better than plates and cups. If a district is badly bombed but the conditions do not warrant the operation of emergency plans, local caterers will be able to call for supplies of hot stew in bulk from establishments equipped for big scale production.

Destruction at Museum of Royal College of Surgeons

Largely irreparable damage was done by German bombs to the greatest pathologic and anatomic museum in the world. Sir St. Clair Thomson has made a report on the specimens illustrating the surgery of the ear, nose and throat. For many years the museum assembled these specimens and received from eminent specialists invaluable collections representing their life work. One of the earliest gifts of normal anatomy was received from the aurist Toynbee, who presented his 300 specimens of the anatomy of the temporal bone. This addition was greatly enriched when Arthur Cheate presented his unrivaled series of sections of the temporal bone. Both these collections have been severely damaged. The basis of the rhinologic section of the museum was secured when the British obtained the large collection made by Onodi of Budapest illustrating the anatomy of the nose and accessory sinuses. It has been heavily damaged, but about 95 specimens are intact and the others can be replaced, as they represent normal anatomy. The 14 specimens of the anatomy of the paranasal sinuses recently presented by the late Professor Hajek are intact. He was able to escape from Vienna about two years ago and with the generous help of American and British colleagues reached London. Here through the help of his confrères he spent his last two years, during which time he enjoyed the liberty which he so much appreciated.

When he escaped from Vienna, he and his wife had their gold watches taken from them and he was allowed to bring only money equivalent to \$2.50. Yet he managed to bring 14 specimens of his collection of rare irregularities of the anatomy of the nasal sinuses. The rest of his 150 specimens had to be left in Austria. The 14 formed part of the specimens he had shown during fifty years to his classes. As a token of his gratitude for deliverance from the city in which he had long been a famous teacher he presented the specimens. The valuable addition to the museum by V. E. Negus of the specimens forming the foundation of his classic study on the comparative anatomy and physiology of the larynx has escaped damage.

International Standard for Vitamin E

An international standard for vitamin E has been established. As for vitamins A, B, C and D the National Institute of Medical Research, London, acting on behalf of the Health Organization of the League of Nations, has undertaken its supply to laboratories and research workers throughout the world. Synthetic racemic alpha tocopherol acetate has been adopted as the international standard for the vitamin. Investigation of its chemical, physical and biologic properties, its suitability as an international standard and its application in biologic assay was performed at the request of the Health Organization of the League of Nations by the vitamin E subcommittee of the accessory food factors committee of the Lister Institute and the Medical Research Council. The subcommittee obtained the cooperation of experts in fourteen laboratories in Europe and America. It recommends that the international unit for vitamin E should be defined as the specific activity of 1 mg. of the standard preparation. This is the average amount, administered by mouth, which prevents resorption gestation in rats deprived of vitamin E.

In normal times the results of the cooperative investigation would have been submitted for discussion at the third international conference on vitamin standardization, which had been arranged for the autumn of 1939, but because of the war it was not held. However, the recommendations have been placed before the members available of the League of Nations Permanent Committee on Biological Standardization and the International Conference on Vitamin Standardization. These have taken the responsibility of adopting the proposed standard, definition of the international unit and the authorizing of the National Institute of Medical Research to proceed with the distribution of the standard. This is issued as a solution in olive oil of the strength of 0.1 Gm. containing 1 international unit. In countries with national control centers it will be supplied to their directors for distribution. It will also be supplied to laboratories and research workers in Britain and in countries where national control centers have not yet been set up. Applications should be made to the Department of Biological Standards, National Institute for Medical Research, Hampstead, London, N.W. 3.

Control of the Sale of Nostrums

The Pharmacy and Medicines Act of 1941 stringently controls the sale of secret remedies. The Ministry of Health has now issued a circular to the food and drug authorities drawing their attention to the power conferred on them to prohibit the advertisements calculated to lead to the use of articles for the treatment of Bright's disease, cataract, diabetes, epilepsy or fits, glaucoma, locomotor ataxia, paralysis or tuberculosis. Similar power is conferred in relation to articles for procuring miscarriage. The act further makes compulsory the disclosure by appropriate means of the composition of medicines sold by retail other than when prescribed, made up and supplied for a particular person. Because of the war, the enforcement of the last provision is postponed until July 1942.

RIO DE JANEIRO

(From Our Regular Correspondent)

Dec. 22, 1941.

Typhus Fever in Brazil

Since 1929 Lemos Monteiro of the Butantan Institute has ascertained by laboratory procedures the existence of several cases of a typhus-like rickettsiosis in the state of São Paulo. In 1932 he demonstrated with the collaboration of Parker and Davis and of Dyer of the United States by cross immunization that São Paulo typhus and Rocky Mountain spotted fever are identical. In 1934 J. A. Moreira and Octavio Magalhaes reported a few cases of typhus in the state of Minas Gerais, and in 1939 J. Travassos and E. Dias of the Oswaldo Cruz Institute proved experimentally that Minas Gerais typhus and Rocky Mountain spotted fever are identical too. Now Drs. J. Tostes and G. Bretz have reported for the first time, in a rural section of the state of Rio de Janeiro, a small outbreak of a disease that, from the clinical, epidemiologic and experimental standpoints is very similar to the Rocky Mountain spotted fever that is known to occur in the states of São Paulo and Minas Gerais. The rickettsial nature of the disease was well established through the peritoneal inoculation in guinea pigs of blood from the patients suffering from the infection. In the opinion of the authors the picture presented by the animals shows a close relationship between the Rio de Janeiro virus and that of Rocky Mountain spotted fever. The incubation time varies from two to six days. The animals show high fever (40-41 C., or 104-105.8 F.) and about 85 per cent die around the end of the first week. A high percentage of male guinea pigs develop scrotal reaction followed frequently by necrosis of the scrotum. The blood is infective during the period of high fever, reproducing the disease when inoculated in other animals. The brain shows a high virus concentration and, stored at a low temperature (-4 C.) is used for reinoculations. The most important finding at autopsy is the enlarged and darkened spleen. It is also frequent to find enlarged lymph nodes and swelling of the subcutaneous connective tissue. The rickettsias are usually found in the endothelial cells of the peritoneal sheet. The Weil-Felix reaction with *Proteus* 0x19 was positive in 5 out of 6 patients examined. The authors have made extensive researches to discover the vector of the disease. The experiment with ticks of the infected area have given till now negative results. The identification of the virus is still incomplete, but the authors are inclined to think that the virus is of the São Paulo and the Minas Gerais strains, and so of western Rocky Mountain spotted fever as well.

The Yellow Fever Situation

In all Brazil as in the whole Western Hemisphere there have been no reports of cases of yellow fever of the urban type during 1941 and in the previous three years as well. Credit must go to those who have perfected control methods so successfully begun in this hemisphere by Gorgas and Oswaldo Cruz. Attention now centers on jungle yellow fever, which is the same disease as urban yellow fever, but with this distinguishing epidemiologic characteristic that in its special forest environment it is not transmitted by *Aedes aegypti*. Risk of yellow fever epidemics will remain as long as the jungle type of the disease persists. During the year 1941 anti-*aegypti* measures have been intensified throughout large areas and many additional districts are now apparently free from this mosquito. There have been advances in the detection of yellow fever, and this point is very important as the failure to suspect the disease has caused the loss of valuable time in the past. It is no longer sufficient to accept the opinion of the clinician, even experienced. Happily the laboratory is now able to give con-

clusive information, even in clinically mild or quite atypical cases, through viscerotomy and protection tests. During the past epidemic season 149 viscerotomy proved cases occurred in rural sections of the states of Rio de Janeiro (4) and Espírito Santo (145). Vaccination was continued on a large scale, the total since the beginning of the use of the procedure almost reaching 2 million vaccinations. Some time during the year 1940 it became apparent that the vaccine being used was not adequately protecting the inoculated persons against the infection, and the fact has been confirmed by postvaccination protection tests. The vaccination effort was reduced while studies were being made to determine the causes of the failure. Fortunately the difficulties in the preparation of a suitable vaccine have been overcome and results comparable to those reported previously were once more obtained. According to the new distribution of tasks, since the reorganization of the federal department of health reported in a previous letter (*THE JOURNAL*, July 12, 1941, p. 132) the yellow fever service of the department has assumed full responsibility for the anti-*aegypti* work, for the viscerotomy and for field vaccination, while the International Health Board of the Rockefeller Foundation continues to cooperate in the epidemiologic and laboratory studies of the disease and in the preparation of vaccine.

Progress in the Pharmaceutical Industry

The chemical-pharmaceutical industry has been in full development in Brazil, since the beginning of World War II. In 1940 the drug and pharmaceutical products took second place, by value, among the exported manufactured goods. At the head of the list are the medicinal oils and emulsions, as well as aqueous and alcoholic extracts of medicinal plants, the last ones forming an important field, as the flora of Brazil is very diversified and rich. The increase over the year 1939 represents more than 400 per cent. Mexico, Peru and Colombia, in this order, are the countries that imported most from Brazil in the field of drugs and medicinal preparations. A very recent development in this field is the report, from the chemical laboratory of the Department of Agriculture, that the liver of "cação"—*Mustelus vulgaris*—a large sharklike fish commonly found off the coast of northern Brazil, is rich in vitamin A. The analysis demonstrated an average potency of about 20,000 international units per gram.

BUENOS AIRES

(From Our Regular Correspondent)

Oct. 15, 1941.

Loan for Health Department in Chile

The government of Chile has received the approval of the parliament for a loan of 500 million Chilean pesos (\$20,000,000) for public health work, more especially for the construction of hospitals, works of sanitation, mother and child protection, a campaign against venereal diseases and tuberculosis and finally the industrialization of lands. Chile has perhaps the highest mortality rate in the world. The morbidity is likewise shockingly high, particularly as regards tuberculosis, syphilis and infectious diseases. These influences incapacitate 20 per cent of the population for working. Chile has a shortage of twenty thousand hospital beds. The obstetric facilities cannot accommodate even 60 per cent of the parturient women. Patients with mental diseases are inadequately provided for. Hospitals of from twenty-five to two hundred and forty beds are urgently required in twenty-eight cities, and insane asylums need equipment. This will require 300 million Chilean pesos (\$12,000,000).

The infant mortality is enormous, as is the number of illegitimate children, forty thousand of whom are without parents. Only 30 per cent of the population live in hygienically unobjectionable towns and 56 per cent in localities which have no hygienic facilities whatever. Of the vegetables marketed in

Santiago de Chile, 80 per cent have been fertilized with sewage. To remedy this situation, sewerage systems must be installed in one hundred and seventy localities and drinking water must be provided for seventy-four. The expenses involved in this are estimated at 90 million Chilean pesos (\$3,600,000). The country has 400,000 syphilitic patients. Facilities for hospitalization, treatment, isolation and education of these patients are urgently needed. The expenses involved are estimated at 90 million Chilean pesos. Chile has about 200,000 tuberculous patients with a mortality of 400 per hundred thousand of the population. There is a shortage of six thousand beds for tuberculous patients. An efficient campaign against tuberculosis will require 100 million Chilean pesos (\$4,000,000).

Menarche in Buenos Aires

Dr. Halperin Pines recently sought to determine the question of the age at which girls in Buenos Aires first menstruate by examining 10,710 Argentine, Spanish and Italian girls in the population. The results are given in the following tabulation:

Age at Initial Menstruation	No. of Cases	Per Cent
9.....	28	0.2
10.....	156	1.45
11.....	955	8.9
12.....	2,011	18.7
13.....	3,142	29.5
14.....	2,456	22.9
15.....	1,192	11.7
16.....	456	4.2
17.....	204	1.9
18.....	90	0.8
19.....	20	0.1

In 1 case menstruation set in at 7 years, in 3 cases at 8 years and in 3 at 20 years. In the majority of cases, accordingly, menstruation began with the thirteenth year. In a similar study, made by Ries and Bueno of 2,947 Argentine children in 1935, age 14 was found to be the initial age of menstruation in most of them. A further analysis was made of 886 Argentine children, most of them belonging to the best social levels. This study gave the following statistical picture:

Age at Menstruation	No. of Cases	Per Cent
8.....	1	0.11
9.....	5	0.56
10.....	33	3.7
11.....	170	19.1
12.....	205	23.2
13.....	253	28.4
14.....	121	13.6
15.....	34	3.8
16.....	10	1.1
17.....	8	0.9
18.....
19.....	1	0.1

These figures indicate that menstruation sets in at an earlier age in girls in the economically higher brackets.

The Spanish children belonging to the poorer classes begin to menstruate most frequently when 14 and 15 years old, at an age later than that of Argentine and Italian girls in the population. Among these, menstruation sets in in Italian girls mostly at the thirteenth and fourteenth year age level.

News

The Rockefeller Foundation has granted to the physiologic institute of the university of Córdoba \$1,500 for the purchase of apparatus and animals for studies on the physiology of the sex life of South American monkeys.

Chile has established the Servicio Nacional de Salubridad Pública, which is to control all sanitary organizations that are concerned with prophylaxis and health protection. The new

organization will take over a great part of the activity which hitherto was handled by the cities, particularly in the control of foodstuffs, in the health inspection of housing facilities, industries and so on.

A Buenos Aires firm (Iturrat) has donated 20,000 pesos (\$6,000) for the department of tuberculosis in the university of Buenos Aires to be used to support social work.

At the suggestion of the director of the Instituto Osvaldo Cruz in Rio de Janeiro, Dr. César Pinto, it has been planned to found a Sociedad Internacional contra la Hidatosis. A meeting of Argentine, Brazilian and Uruguayan physicians will be held in Uruguay to promote this matter.

The council of the University of Buenos Aires, in agreement with the faculty of medicine, has decided to celebrate the "Dia del Medico" every year on October 18.

The faculty of medicine of the University of Buenos Aires has decided to create a bureau which is to cultivate relations with American universities. This organization is connected with the dean's office and is to maintain close scientific, administrative and scholastic relationships with all faculties of medicine of the three Americas.

Prof. Juan Ramón Beltrán, professor of medical history in Buenos Aires, at the invitation of the faculty of medicine of Rio de Janeiro, is giving a series of lectures in Rio de Janeiro on medicine in ancient Greece.

Dr. Alvaro E. Bence received from the Asociación Argentina para el Progreso de las Ciencias a stipend for the study of bronchoscopy with Chevalier L. Jackson and Louis Clerf in Philadelphia.

Dr. Pedro Belou, professor of anatomy in the faculty of medicine of Buenos Aires, will lecture during the coming months in the leading cities of the South and Central American countries in behalf of Pan American medical solidarity. He has also been invited by several universities in the United States. While in this country he is planning to have English adaptations made of scientific films on neuraxis and the arterial system.

Deaths

Dr. Benigno T. Escobar, professor of clinical surgery at the faculty of medicine of the University of Asunción, Paraguay, aged 63, died in Buenos Aires, where he was conducting studies.

Prof. Dr. Alejandro Centeno, internist at the faculty of medicine of the University of Córdoba, Argentina, died recently.

Marriages

ROBERT VAN ZANDT BUCKLIN, Evanston, Ill., to Miss Rosemary Leonore Heiny in Tacoma, Wash., in October 1941.

JAMES LUTHER SPENCER JR. to Miss Frances Elizabeth League, both of Charleston, S. C., Sept. 27, 1941.

CARL T. BUEHLER JR., Halstead, Kan., to Miss Maxine James of Burlington Junction, Mo., in September 1941.

WILLIAM HUBBARD GRIMES JR., Colquitt, Ga., to Miss Claire Rosalinde Richards of Atlanta, Sept. 20, 1941.

DAVID SHIELDS CARROLL, Morristown, Tenn., to Miss Mary Kathryn McGuire of Memphis, Nov. 8, 1941.

NORMAN W. HENRY JR., Mooresville, N. C., to Miss Ethel R. Black of Vineland, N. J., Aug. 28, 1941.

KARL E. JOHNSON, San Diego, to Miss Catharine M. Harris of Santa Barbara, Calif., Sept. 20, 1941.

McLEMORE BIRDSONG, Charlottesville, Va., to Miss Charlotte Spain of Petersburg in October 1941.

ARNOLD F. STRAUSS to Miss Marjory Ware Spindle, both of Norfolk, Va., in October 1941.

HERBERT HOLDEN THOMAS, Huntsville, Ala., to Miss Louise Petry of Eufaula, Sept. 1, 1941.

JAMES F. LYONS, Miami, Fla., to Miss Patricia Scmple of Coral Gables in August 1941.

Deaths

Walter Lindsay Niles ☉ New York; Cornell University Medical College, New York, 1902; since 1916 professor of clinical medicine and from 1919 to 1928 dean, and since October 1941 acting dean, at his alma mater; member of the Association of American Physicians and the American Clinical and Climatological Association; vice president of the New York Academy of Medicine from 1934 to 1936, on the board of trustees from 1928 to 1932 and again since 1936 and chairman since 1937; member of the Joint Administrative Board of New York Hospital, Cornell Medical College Association; attending physician, New York Hospital; consulting physician, Southampton (N. Y.) Hospital, Jamaica (N. Y.) Hospital, Nassau Hospital, Mineola; Bellevue Hospital, New York Infirmary for Women and Children, and Memorial Hospital; author of the chapter on intestinal diseases in Cecil's Medicine; aged 63; died, Dec. 22, 1941, of cerebral hemorrhage.

Adam Gillespie Nichol, Nashville, Tenn.; University of Nashville Medical Department, 1898; member of the Tennessee State Medical Association, Clinical Orthopaedic Society and the American Academy of Orthopaedic Surgeons; formerly assistant professor of orthopedic surgery at the Vanderbilt University School of Medicine and assistant professor of operative surgery at his alma mater; for many years on the staff of the Nashville General Hospital; member of the board of trustees of the Davidson County Tuberculosis Hospital; member of the advisory board of the Junior League Home for Crippled Children, formerly known as the Convalescent Home for Crippled Children, of which he was head of the staff; aged 65; died, Nov. 14, 1941, in Dallas, Texas, of cerebral hemorrhage.

Marius Liborius Abbene, Brooklyn; New York Homeopathic Medical College and Flower Hospital, New York, 1914; member of the Medical Society of the State of New York; fellow of the American College of Surgeons; instructor of obstetrics and gynecology at the Long Island College of Medicine; obstetrician, Bushwick Hospital; associate gynecologist and obstetrician, St. Mary's Hospital; associate gynecologist and obstetrician, and chief, gynecological and obstetrical clinic, Greenpoint Hospital; physician for the local draft board in the first and second world wars; aged 55; died, Dec. 9, 1941, of coronary thrombosis.

Casper Walker Jennings, Greensboro, N. C.; Medical College of Virginia, Richmond, 1916; member of the Medical Society of the State of North Carolina and the American Academy of Ophthalmology and Otolaryngology; formerly secretary of the Guilford County Medical Society; past president and secretary of the North Carolina Eye, Ear, Nose and Throat Society; on the staffs of the Wesley Long Hospital, St. Leo's Hospital, Sternberger Hospital for Women and Children, and Piedmont Memorial Hospital; aged 48; died, Nov. 22, 1941, of acute dilatation of the heart.

Greer Baughman ☉ Richmond, Va.; Medical College of Virginia, Richmond, 1897; professor of obstetrics at his alma mater; member of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons and the Southern Surgical Association; fellow of the American College of Surgeons; visiting obstetrician, Stuart Circle Hospital; consulting obstetrician, Memorial and St. Philip hospitals; formerly surgeon to the fire department of Richmond; aged 67; died, Dec. 2, 1941, of chronic nephritis and uremia.

Eugene John Bozsán ☉ New York; Magyar Királyi Pázmány Petrus Tudományegyetem Orvosi Fakultása, Budapest, Hungary, 1913; member of the American Association for the Surgery of Trauma; fellow of the American College of Surgeons; served with the Austrian-Hungarian Army during the World War; on the staffs of the Hospital for Joint Diseases and the Morrisania City Hospital; aged 51; died, Dec. 4, 1941.

Hampton Pierson Howell ☉ New York; College of Physicians and Surgeons, medical department of Columbia College, New York, 1894; member of the American Laryngological, Rhinological and Otolological Society; attending otolaryngologist of the Roosevelt Hospital from 1929 to 1934 and consultant otolaryngologist since 1935; aged 71; died, Dec. 11, 1941, at his home in Westhampton Beach, N. Y.

Jesse Bundren Helm ☉ Medical Director, Captain, United States Navy, Washington, D. C.; University of Louisville (Ky.) Medical Department, 1911; fellow of the American College of

Physicians; entered the naval service July 20, 1913 and was retired on Aug. 1, 1940 for disability incurred in the line of duty; aged 56; died, Nov. 26, 1941, in the Garfield Hospital of hypertensive heart disease.

Maurice Schneider, Chicago; Northwestern University Medical School, Chicago, 1928; was a member of the associate staff of the teaching faculty of the Cook County Graduate School of Medicine, in the division of diseases of children; associate on the staff of the Cook County Children's Hospital; aged 38; died, Dec. 2, 1941, in the Mount Sinai Hospital.

Henry Farrer Owsley, Poughkeepsie, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1896; veteran of the Spanish-American War; aged 70; died, Nov. 27, 1941, in the Westchester Division of the New York Hospital, White Plains, of bronchopneumonia and arteriosclerosis.

Henry Ernest Paul, Toronto, Ont., Canada; Queen's University Faculty of Medicine, Kingston, 1901; member of the American Urological Association; served during the World War; aged 65; on the staffs of the Christie Street Hospital and St. Joseph's Hospital, where he died, Nov. 7, 1941.

George Wallace Elliott, Vancouver, B. C., Canada; Manitoba Medical College, Winnipeg, 1899; formerly member of the Winnipeg police force; at one time medical immigration officer of the Canadian government at Ellis Island, N. Y., and at Portland, Maine; aged 77; died, Oct. 21, 1941.

George Edwin Shetrone, Shillington, Pa.; Hahnemann Medical College and Hospital, Philadelphia, 1921; member of the Medical Society of the State of Pennsylvania; physician for the county schools; on the staff of the Homeopathic Hospital, Reading; aged 43; died, Nov. 6, 1941.

John Trantham Stephenson, Emmett, W. Va.; University of Georgia Medical Department, Augusta, 1925; member of the West Virginia State Medical Association; served during the World War; formerly a physician in the Indian Service; aged 53; died, Nov. 14, 1941.

James Tilden Christian, Sacramento, Calif.; Cooper Medical College, San Francisco, 1902; member of the California Medical Association; formerly county health officer; served during the World War; aged 63; died, Nov. 30, 1941, in a hospital at San Francisco.

Charles Ashton Webster, Yarmouth, N. S., Canada; College of Physicians and Surgeons, medical department of Columbia College, New York, 1886; fellow of the American College of Surgeons; visiting surgeon, Yarmouth Hospital; aged 77; died, Nov. 22, 1941.

John Hill Hammond ☉ La Fayette, Ga.; Jefferson Medical College of Philadelphia, 1883; an Affiliate Fellow of the American Medical Association; for many years chairman of the city board of education; formerly county health commissioner; aged 85; died, Nov. 26, 1941.

James A. Dorsett, Lucedale, Miss.; Atlanta (Ga.) College of Physicians and Surgeons, 1902; member of the Mississippi State Medical Association; at one time mayor of Lucedale; aged 64; died, Nov. 5, 1941, in the Mobile Infirmary, Mobile, Ala.

Henry Hunt Duke, Denair, Calif.; Hospital College of Medicine, Louisville, Ky., 1899; formerly passed assistant surgeon in the United States Public Health Service Reserve; veteran of the Spanish-American and World wars; aged 68; died, Oct. 11, 1941.

Allen Hanson Blake ☉ Somerville, Mass.; Harvard Medical School, Boston, 1904; member of the New England Roentgen Ray Society and the Radiological Society of North America, Inc., on the staff of the Somerville Hospital; aged 60; died, Dec. 9, 1941.

James Eugene Dwyer, Milwaukee; University of Maryland School of Medicine, Baltimore, 1905; served during the World War; aged 64; on the staff of the Veterans Administration Facility, where he died, Nov. 14, 1941, of nephrosclerosis.

William Otto Bailey, East Orange, N. J.; Eclectic Medical College of the City of New York, 1887; University of the City of New York Medical Department, 1889; aged 85; died, Dec. 7, 1941, of cerebral hemorrhage and arteriosclerosis.

Wallace Kasson Harrison ☉ Chicago; Bennett Medical College, Chicago, 1877; College of Physicians and Surgeons of Chicago, 1884; an Affiliate Fellow of the American Medical Association; aged 93; died, Dec. 7, 1941.

Jesse Bird, Oklahoma City; University of Louisville (Ky.) Medical Department, 1896; member of the Oklahoma State Medical Association; aged 66; on the staff of the Samaritan Hospital, where he died, Dec. 9, 1941.

S. Dwight Stevenson, Columbus, Ohio; Medical College of Ohio, Cincinnati, 1890; member of the Ohio State Medical Association; aged 75; died, Nov. 26, 1941, in the White Cross Hospital following an appendectomy.

Warren Alexander Harper, Zapata, Texas; University of Tennessee Medical Department, Nashville, 1892; formerly acting assistant surgeon, United States Public Health Service; aged 75; died, Nov. 29, 1941, in Austin.

Ezra Eugene Osburn, Broughton, Ill.; St. Louis College of Physicians and Surgeons, 1904; aged 59; died, Dec. 1, 1941, in the Ferrell Hospital, El Dorado, of pneumonia and of injuries received in an automobile accident.

J. Michaux Corpening, Harrington, Wash.; University of Nashville (Tenn.) Medical Department, 1898; member of the Washington State Medical Association; aged 74; died, Nov. 1, 1941, of coronary thrombosis.

Winsor W. Warriner, Antioch, Ill.; Northwestern University Medical School, Chicago, 1902; aged 67; died, Nov. 30, 1941, in the Victory Memorial Hospital, Waukegan, of peritonitis and acute appendicitis.

Thomas Chason Ⓢ Donalsonville, Ga.; Vanderbilt University School of Medicine, Nashville, Tenn., 1892; at one time medical director and superintendent of Chason's Hospital; aged 68; died in November 1941.

Chalmer Middleton Harger, Seattle; University of Colorado School of Medicine, Denver, 1921; member of the Washington State Medical Association; aged 50; died, Nov. 13, 1941, of coronary thrombosis.

Helen P. Beattie Tennies, Green Bay, Wis.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1904; aged 60; died, Oct. 30, 1941, of chronic myocarditis.

Leo John Nicola Ⓢ Chicago; Chicago Medical School, 1926; aged 41; on the staff of St. Francis Hospital, Evanston, Ill., where he died, Nov. 8, 1941, of patent foramen ovale and cirrhosis of the liver.

Clarence La Motte Boston, Noxen, Pa.; University of the City of New York Medical Department, 1884; member of the Medical Society of the State of Pennsylvania; aged 82; died, Dec. 1, 1941.

John A. Walker, Du Pont, Wash.; Northwestern University Medical School, Chicago, 1893; member of the Washington State Medical Association; aged 72; died, Nov. 15, 1941, in Phoenix, Ariz.

Benjamin Franklin Boyer, Riegelsville, Pa.; Long Island College Hospital, Brooklyn, 1867; Bellevue Hospital Medical College, New York, 1868; Civil War veteran; aged 99; died, Dec. 11, 1941.

Edgar Allen Cowles, Detroit Township, Minn.; University of Tennessee Medical Department, Nashville, 1892 and 1893; also a dentist; aged 80; died, Sept. 1, 1941, of hypertensive heart disease.

John Ellsworth Suter, Piedmont, W. Va.; College of Physicians and Surgeons, Baltimore, 1893; formerly mayor; bank president; aged 71; died, Nov. 29, 1941, of chronic myocarditis.

Harry Francis Rubel, Des Moines, Iowa; College of Physicians and Surgeons, School of Medicine of the University of Illinois, Chicago, 1904; aged 63; died, Nov. 25, 1941, of cirrhosis of the liver.

James Blaine Padgham, Ocheyedan, Iowa; State University of Iowa College of Medicine, Iowa City, 1909; member of the Iowa State Medical Society; aged 58; died, Nov. 9, 1941, of uremia.

Leon Knight Harding, Hopkinsville, Ky.; University of Tennessee Medical Department, Nashville, 1900; also a minister; aged 69; died, Nov. 29, 1941, in a hospital at Atlanta, Ga.

Walter Wynn Barnett, Fort Wayne, Ind.; Fort Wayne College of Medicine, 1886; veteran of the Spanish-American War; formerly county coroner; aged 84; died, Dec. 1, 1941.

James Lowry McBride Ⓢ Zanesville, Ind.; Medical College of Indiana, Indianapolis, 1892; served during the World War; aged 76; died, Nov. 29, 1941, of coronary thrombosis.

Joseph H. Satterthwaite, Trenton, N. J.; Hahnemann Medical College of Philadelphia, 1883; died, Nov. 23, 1941, in the William McKinley Memorial Hospital of heart disease.

John William Long, Sallis, Miss.; Kentucky School of Medicine, Louisville, 1908; member of the Mississippi State Medical Association; aged 56; died in November 1941.

James Malvern Halsey, Charleston, S. C.; Medical College of the State of South Carolina, Charleston, 1937; aged 30; was found dead, Nov. 23, 1941, of a bullet wound.

William Edward McDougal, Savannah, Tenn.; Vanderbilt University School of Medicine, Nashville, 1877; aged 87; died, November 19, at Memphis of cerebral hemorrhage.

George Brannan Allen Ⓢ South Bend, Ind.; Northwestern University Medical School, Chicago, 1916; aged 53; died, Dec. 4, 1941, of angina pectoris and coronary sclerosis.

Arminius Neulaender, Brooklyn; Magyar Királyi Pázmány Petrus Tudományegyetem Orvosi Fakultása, Budapest, Hungary, 1898; aged 67; died, Nov. 21, 1941.

Spurgeon Floyd Priestley, Stockton, Calif.; Barnes Medical College, St. Louis, 1898; member of the California Medical Association; aged 73; died, Nov. 23, 1941.

Paul Clifton Alexander, Redwood City, Calif.; Cooper Medical College, San Francisco, 1900; aged 67; died, Dec. 6, 1941, in the Palo Alto (Calif.) Hospital.

Oscar Leonard Spencer, Fiskeville, R. I.; Boston University School of Medicine, 1911; aged 75; died, Nov. 27, 1941, at Cranston of cardiorenal disease.

Frank H. Sidwell, Baltimore; University of Maryland School of Medicine, Baltimore, 1880; died, Nov. 22, 1941, in the Maryland General Hospital.

William Hubert Arrants, Sweetwater, Tenn.; University of Nashville (Tenn.) Medical Department, 1910; aged 59; died, Dec. 13, 1941, of myocarditis.

Erasmus Lear Reigle, Bloomsbury, N. J.; Jefferson Medical College of Philadelphia, 1889; aged 78; died, Nov. 29, 1941, in Easton, Pa., of empyema.

Esca D. Pope Ⓢ Hillister, Texas; Kentucky School of Medicine, Louisville, 1897; aged 69; died, Nov. 26, 1941, of cerebral hemorrhage.

James Sidney Smith, Greenville, Texas (licensed in Texas, under the Act of 1907); aged 86; died in November in a hospital at Dallas.

Ernest Bartine Smith, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1900; aged 65; died, Nov. 28, 1941.

Frank C. Houser, Lincoln, Ill.; Bennett College of Eclectic Medicine and Surgery, Chicago, 1887; aged 83; died, Nov. 26, 1941.

Amelia Landis Hess, Philadelphia; Woman's Medical College of Pennsylvania, Philadelphia, 1892; aged 83; died, Nov. 25, 1941.

Guy Edward Beard, Algonquin, Ill.; Northwestern University Medical School, Chicago, 1910; aged 61; died, Dec. 11, 1941.

William Henry Kensinger, Miami, Fla.; Jefferson Medical College of Philadelphia, 1889; aged 85; died, Nov. 23, 1941.

Julius Purcell Haynes, Toledo, Ohio; Dartmouth Medical School, Hanover, N. H., 1888; aged 75; died, Nov. 17, 1941.

James Alexander Morrow, Philadelphia; Baltimore University School of Medicine, 1889; aged 81; died, Nov. 28, 1941.

Fred William Watt, Bieber, Calif.; Cooper Medical College, San Francisco, 1901; aged 66; died in November 1941.

Archie Wilson Barker, Springfield, Ill.; Barnes Medical College, St. Louis, 1899; aged 74; died, Dec. 4, 1941.

Haller Francis Keables, Burbank, Calif.; Rush Medical College, Chicago, 1890; aged 76; died, Nov. 2, 1941.

Esther Mitchell, Mount Sterling, Ky.; Rush Medical College, Chicago, 1903; aged 75; died, Nov. 30, 1941.

William K. Yorks, Chicago; Hering Medical College, Chicago, 1900; aged 76; died, Nov. 26, 1941.

Frederick Dow Lyon, Boston; Harvard Medical School, Boston, 1896; aged 72; died, Nov. 27, 1941.

Bureau of Investigation

CEASE AND DESIST ORDERS

Abstracts of Certain Federal Trade Commission Releases

The work of the Federal Trade Commission, in helping to protect the public against misrepresentation or fraud in the medical as well as other fields, has been greatly extended by the provisions of the Wheeler-Lea Amendment to the Federal Trade Commission Act. The Food, Drug and Cosmetic Act of 1938 added to the Food and Drug Administration's control of the advertising claims and statements made on the labels of medicines or on the carton or in the accompanying leaflet, whereas what might be termed collateral advertising, that which appears in circulars, newspapers and magazines and over the air, comes more actively under the purview of the Federal Trade Commission, by virtue of the Wheeler-Lea Amendment.

THE JOURNAL has at various times commented on the activities of the Federal Trade Commission in this connection, even before the Wheeler-Lea Amendment gave it its added rights. In some cases the Commission may accept from the person or concern involved a stipulation that the objectionable practices or claims cited will be discontinued. In other cases the Commission issues what is known as a Cease and Desist Order, in which the individual, manufacturer or distributor cited is ordered to cease and desist from practices which have been declared objectionable.

Abstracts of some of the orders issued in 1941 follow:

Alcoban.—This was exploited as a treatment for alcoholism by Edwin L. Leisenring, trading as U. S. Drug and Sales Company, U. S. Drug Laboratories and U. S. Drug Company, and Gordon Leisenring, both of Denver. The Federal Trade Commission ordered these individuals in January 1941 to cease representing that the product is a safe and competent treatment for alcoholism or that it removes the desire for alcoholic stimulants. They also were to discontinue any advertisements which fail to reveal that the use of Alcoban may result in serious injury to the nerves, tissues and lungs and may produce toxic conditions in the body.

Bowe's Tablets.—The advertising of this nostrum by R. G. Bowe and W. W. Hartman, trading as Bowe & Hartman, Toledo, Ohio, represented that some twenty ailments, including ulcers of the stomach, duodenum and intestine are due to or persist solely because of hyperacidity or the presence of excess acid in the body and that the Bowe product is a cure or remedy for hyperacidity and consequently for the ailments mentioned. In January 1941 the Federal Trade Commission ordered the promoters of Bowe's Tablets to discontinue making these misrepresentations and setting themselves forth as manufacturing pharmacists or as making the preparation that they sell.

Eucozone.—This was put out by Eucozone Laboratories, Inc., and by its successor, Universal Eucozone of America, Inc., Detroit. In March 1941 the Federal Trade Commission ordered the last-named concern to cease representing that the product is a germicide or has any therapeutic action beyond that of a mild antiseptic and counterirritant; that it is an internal antiseptic or will supply oxygen to the bloodstream; that it is of any value in treating colds, catarrh, sinus infection, rose fever, hay fever or localized congestions associated with such conditions, except that afforded by a mild antiseptic and counterirritant; that it is a cure or remedy for athlete's foot or has any action thereon, except as a mild antiseptic; that it is of any use in treating itch, carbuncles, irritations of the skin or hemorrhoids or is nonpoisonous or nonirritating and suitable or safe for internal use or that it is an ozonide of eucalyptol or has any therapeutic properties other than those of ordinary oil of eucalyptol or eucalyptol.

George's Compound.—J. Lawrence Walker and T. Kyle Woodward, trading as Walker and Woodward, and Nick A. George and John G. Brown, all of Casper, Wyo., promoted this product as having value in the treatment of all ailments except cancer and diabetes. Since the Federal Trade Commission's findings showed that the stuff was useless for the long list of disorders named, except as a temporary palliative, the defendants were ordered in February 1941 to cease and desist from making misrepresentations in their advertising. Incidentally, in at least 2 cases on record, George's Compound has been declared to violate the Pure Food and Drugs Act because of false claims made in or on the trade package. The first case was abstracted in this department of THE JOURNAL Dec. 23, 1939, page 2339.

Kongolene.—In January 1941 the Federal Trade Commission ordered the Kongo Chemical Company, Inc., of New York to discontinue certain misrepresentations in its advertising of this hair preparation. Among these were that the product is harmless to use, is a "purely vegetable product," will permanently straighten the hair or contribute to such straightening in any way other than by softening the hair temporarily, will promote the growth of the hair and prevent its falling out, will cure dandruff, will benefit the offspring of the user and is "the greatest discovery of the age." The concern also was ordered to discontinue any advertisements which failed to reveal that the use of the stuff might result in severe caustic action on the skin and scalp, with resulting burns. In April 1941

the Commission added to the order the proviso that the advertising of Kongolene need contain only a statement that the product should be used only as directed on the label, when such label contains a warning that the preparation might have a caustic action on the skin and scalp with resulting burns, and certain directions for the safe and proper use of Kongolene which were detailed in the original order.

Nu-Mode Products.—These are promoted by Harry S. Benham of Chicago, who has operated under such names as the Zone Company, Active Merchandisers, Active Medicine, Nu-Mode Company and American Medicine Company. In January 1941 the Federal Trade Commission ordered Benham to discontinue advertisements containing certain misrepresentations. Among these were that "Nu-Mode Vaginal Jelly" (also known as "A. M. Vaginal Jelly"), "Nu-Mode Hygiene Tablets," "Vaginal Suppositories and Douche Tablets," and "Speed Nu-Mode Hygiene Douche Tablets" constitute safe and effective preventives of conception or are a guaranteed method of preventing pregnancy; that "Nu-Mode Ladies Womb Supporter" is comfortable, efficient or sanitary or has therapeutic value; that "Athlete's Foot Salve" is a cure or remedy for athlete's foot or has value in its treatment in excess of temporarily relieving symptoms of itching and in some cases destroying superficial fungi; that "A. M. Wonder Salve" is a cure or remedy for eczema or other forms of itch or rash or has value in their treatment in excess of affording temporary relief from symptoms of itching, or that it has any properties effective in preventing infection or in treating ulcers, old sores, leg sores, acne or pimples.

Nuga-Tone.—National Proprietaries, Inc., of Chicago were ordered by the Federal Trade Commission in January 1941 to discontinue advertisements which represent Nuga-Tone as possessing any value in the treatment of nervous disorders or which fail to reveal that the use of the nostrum may result in chronic poisoning, irritation of the kidneys, nervous irritability, neuritis or some other conditions. In November 1937 the Commission likewise had ordered the National Laboratory of Chicago (which was then putting out Nuga-Tone) to discontinue certain false representations about the product, such as that it was an effective remedy for various stomach complaints and could be taken over long periods by any one without harmful results. The Commission also ordered the concern to cease representing itself as a "Laboratory," which may have been the reason that the firm name was changed. A lengthy discussion of Nuga-Tone and of the 2 year old child who had convulsions after swallowing some of the tablets appeared in THE JOURNAL May 17, 1924, page 1628.

Purex.—This product is put out as a germicide by the Purex Corporation, Ltd., Southgate, Calif., which in January 1941 was ordered by the Federal Trade Commission to withdraw from its advertising the misrepresentations that a solution containing any amount of less than 10 per cent of Purex is a competent or effective germicide for treating surface cuts or sores, or that a solution containing 2 tablespoons of Purex to each gallon of water is capable of killing all forms of bacterial life.

ReVigator Products.—In February 1941 the Federal Trade Commission ordered the ReVigator Corporation of Cleveland and its president, E. O. Loeber, to cease making certain misrepresentations in the sale of these. Among them were that the "ReVigator System of Home Treatment for the Scalp and Hair" provides a cure for falling, fading and thinning hair, dandruff and baldness. The Commission's findings were that the use of the "ReVigator Pressure Cap" alone or in combination with the other products in the treatment ("ReVigator Liquid Home Treatment for Scalp and Hair" and "ReVigator Liquid Shampoo") would not accomplish the results claimed and would have no therapeutic value in treating such conditions in excess of cleansing the hair and scalp and temporarily removing accumulated dandruff scales.

Texas Wonder.—For years this product has been represented as a cure for bladder and kidney disorders and has been the subject of actions by the Food and Drug Administration in more than one hundred instances over a period of years, on the charge that the label claims violated the Pure Food and Drugs Act. The first case was abstracted in this department of THE JOURNAL Feb. 22, 1919, page 591. In May 1932 the Federal Trade Commission dismissed a complaint against E. B. Hall and E. W. Hall of St. Louis on the charge of misrepresentations in advertising, at which time the Halls signed a stipulation agreeing to cease and desist from the practices charged. In February 1941 the Commission again was obliged to take action against the Halls and definitely ordered them to discontinue advertising that "Texas Wonder" is of value in the treatment of any of the ailments mentioned (kidney disorders, diabetes, rheumatism, swollen joints, weak or lame back, pains in the back or lumbago) except for such slight symptomatic relief as it may give in cases of swollen joints or pains in the back, because of its mild diuretic properties.

Vendol.—In January 1941 one David H. Fulton, trading as Vendol Company, Baltimore, was ordered by the Federal Trade Commission to eliminate from his advertising certain representations that the Commission declared to be false and misleading, such as that the product is a cure or remedy for constipation, stomach disorders, liver ailments, skin troubles or dyspepsia or is effective therefor, within certain limits; or, without making certain reservations, that the product will cure rheumatism, headaches, excess acidity, palpitation and some other things. In March 1937 David H. Fulton had promised the Commission that he would discontinue certain other misrepresentations in his advertising, such as that Vendol would correct any physical ailment including certain disorders of the stomach, liver and kidneys and that Vendol was prescribed by a physician.

X-Bazin.—This hair remover was represented by Hall & Ruckel, Inc., Brooklyn, as being noneauetic and in all cases entirely harmless. It was claimed that it discouraged the growth or delayed the appearance of hair for a substantial period of time, permanently eradicating hair, producing results essentially different from those obtained by the use of other depilatories and having the endorsement of scientists or physicians. In January 1941 the Federal Trade Commission ordered the concern to discontinue these misrepresentations.

SOME MISCELLANEOUS MEDICAL FRAUDS

A Variety of Schemes Debarred from the Mails

Fraud orders issued by the Post Office Department have frequently been the subject of extensive articles by the Bureau of Investigation in these pages of THE JOURNAL. Following are brief abstracts of some Fraud Orders not dealt with previously.

Bartlett "Cures" for Liquor and Tobacco Habits—These were exploited from Birmingham, England, by a William Bartlett, who also used a Winnipeg, Canada, address and operated under various names including W. Bartlett Co. and Reliance Products. His "Bartlett Tobacco Treatment" was found to consist of gentian root to be chewed and some tablets to be swallowed, each containing more than 2 grains (0.13 Gm.) of quinine sulfate. Those who ordered the "Bartlett Liquor Remedy" received a prescription calling for 90 parts of sodium bicarbonate, 5 parts of powdered cuminum cuminum and 5 parts of powdered cinnamon, to be made up into 150 capsules of 1½ grains (0.1 Gm.) each. Medical experts testified that the most important factors in overcoming the liquor and tobacco habits are the determination and cooperation of the victim and that, since these cannot be supplied by drugs, no mixture could of itself cure either habit. A fraud order debarbing the Bartlett nostrums from the mails was issued on July 30, 1940.

Blanchard's Lotion—This was a curious combination of medical and religious quackery promoted by a Joseph Blanchard, who conducted his mail order scheme from Chicago, New York and Long Beach, Calif. He put out something variously called "Joseph Blanchard's Eczema Lotion" and "Trinity Lotion," which he represented as a cure for eczema, psoriasis, acne, leg ulcers and all infections and irritations of the ear, nose and mouth. With it went some circulars, one known as "Spiritual Copy No. 3," which exhorted in part "Always apply Trinity Lotion for a Spiritual Soul Blessing." Apparently discounting the alleged spiritual value in favor of the material one, the government chemists analyzed the product and reported it to be a slightly acidic, hydroalcoholic, mucilaginous liquid containing 0.04 per cent of mercury, 9.1 per cent of alcohol and an unidentified mixture of gums. As this combination would not cure such comparatively intractable conditions as psoriasis and eczema, the Post Office Department declared the thing a fraud and debarred it from the mails on August 31, 1940. In April 1935 a consignment of "Prof. Joseph Blanchard's Eczema Lotion" from Chicago was declared in a district federal court to be fraudulently represented on the label as an effective treatment for various forms of eczema, psoriasis, ulcers and some other cutaneous disorders. Government chemists reported that it consisted essentially of mercury bichloride, alcohol and water, with small amounts of borax and gum.

"Dr." O. T. Manson—This Waycross (Ga.) Negro charlatan also worked the "numbers" game and sold advice and medicines chiefly among Negro victims. After promising an inquirer to "bring you strong and alive" for \$3 and receiving that sum, he demanded an equal amount in addition to "fix up" the patient. When the second remittance of \$3 was sent, Manson demanded an additional \$2 and, on getting it, sent the customer an assortment of capsules and pills. The composition of both was found to be essentially calomel, aloin and podophyllin. As these are only common laxatives and would not "fix up" certain serious diseases whose symptoms were suggested by the customer, Manson's scheme was declared fraudulent and was debarred from the mails on June 7, 1940.

"Rev. Doc J. H. Thompkins"—This self-styled "spiritualist and divine healer," as well as "world's greatest fortune teller," a Negro, operated first from Columbus, Ga., and later from Phenix City, Ala., selling "lucky hands." These, he claimed, would "Uncross Your Luck, Do Anything You Want Done, Cure Anything You Want Cured, Bring Back Husband, Wife or Friend, and Make You See Wonders, I See All, Tell All, Make All, Know All, Do All." A "lucky hand," for which Thompkins charged from \$15 to \$985, consisted chiefly of "science" of numbers, "religious" literature and a small bag of grayish white powder. Analysis showed this to consist of iron ore, powdered sulfur, ground capsicum, gentian and sage leaves. The customer was told to add a teaspoonful of urine to this daily for three days, "dress" it with perfume and wear it close to the body. As this mixture obviously would not cure anything, a Post Office fraud order was issued against Thompkins on Feb. 29, 1940.

Young and Smit—This New York firm, which designated itself as an importer of medicines originating in the Dutch East Indies, consisted of a Ralph Young and an Antoinette Smit, who sold a long list of nostrums by mail. The chief one seems to have been "Herb Preparation No. 17," which a government analysis showed was a mixture of ground mint leaves, spurge, celery root and a species of bean. It was to be brewed and taken for rheumatism four times a day "until pains disappear." If one was "looking for a pleasant way to help take off excess fat," he was told that "Bali Tea No. 13" is the answer to your prayer! It was reported to consist chiefly of ground leaves and roots of mint, black elder and ginger. For disorders of the kidney and bladder there was "Koemis Koetjing No. 21," which was principally ground mint leaves. For liver troubles the concern sold "Hepatic Tea No. 2," a mixture of ground leaves and roots of herbs known as graptophyllum, hydrocotyle, curcuma, plantago major and blumea balsamifera. For "piles and rectal disturbances" there was "Herbal Preparation No. 9," a mixture of meibomia, cantharaceae, tamarindus, rhubarb and licorice roots and hydrocotyle cantharaceae, with traces of arbus and euphorbia. With it came "Java Lax Herbs No. 7," said to be composed of herbs having irritant laxative qualities. As expert medical testimony showed that none of these nostrums would produce the results claimed for them, a fraud order was issued against their promoters on Dec. 5, 1940.

STIPULATIONS

Agreements Between Federal Trade Commission and Promoters of Various Products

The following items are abstracts of stipulations in which promoters of "patent medicines," cosmetics or medical devices have cooperated with the Federal Trade Commission to the extent of agreeing to discontinue certain misrepresentations in their advertising. These stipulations differ from the "Cease and Desist Orders" of the Commission in that such orders definitely direct the discontinuance of misrepresentations. The abstracts that follow are presented primarily to illustrate the effects of the provisions of the Wheeler-Lea Amendment to the Federal Trade Commission Act on the promotion of such products.

Massagic—This is the brand name for a line of shoes sold by the Weyenberg Shoe Manufacturing Company of Milwaukee, which represented that they would massage and exercise the feet and produce "massaging resilience," cause calluses to vanish and keep the feet "young." In a stipulation signed with the Federal Trade Commission in June 1941 the concern agreed to discontinue these misrepresentations.

Wa-Hoo Bitters—This is put out by a Charles K. Wilson, trading as Old Indian Medicine Company and as Wa-Hoo Medicine Company, Toledo, Ohio. In January 1941 Wilson promised the Federal Trade Commission to cease representing that his product is a tonic or effective treatment for ailments of the blood, nerves, stomach, liver or kidneys or a remedy for rheumatism, gastritis and some other things, or that his "Old Indian Remedy" or "Old Indian Root and Herb Tonic" originated with the Indians before they were acquainted with recognized medical science. In 1916 and 1935 specimens of "Wa-Hoo Bitters" were declared in government courts to violate the Pure Food and Drugs Act because of false and fraudulent claims on the labels. Government chemists reported that analyses of specimens showed them to be aqueous solutions of epsom salt and salicylic acid, with indications of sassafras, gentian and prickly ash.

Valeria's Hair Grower—That this will cause the natural oils of the scalp to be retained or overcome dryness of the scalp, stop excessive dandruff or falling hair or cause hair to grow constitutes advertising misrepresentations which Dave Boston and Willma Boston, trading as Valeria's Products and as Valeria's, Detroit, promised the Federal Trade Commission that they would discontinue in a stipulation that they signed in June 1941.

"Vegetate" Products—These are put out by Vegetates, Inc., of Los Angeles and include "Vege broth," "Vegetate BF 1," "Vegetate Formula No. CC 413" and thirteen other preparations. In February 1941 Vegetates, Inc., stipulated with the Federal Trade Commission that it would cease representing that modern conditions cannot assure the full measure of life sustaining organic minerals in the food one buys or cooks today, that the "Vegetate" formulas are concentrated or contain all the concentrated goodness of nature's own vegetables or of vegetables grown in a specially mineralized soil, or that they give added protection to persons having low resistance. The concern also agreed to cease advertising that "Vegetate 'Carra' Fortified with Vitamin 'A'" is a protection against infection or that "Wheat Germ Oil Perles, Standard Potency Vitamin 'E'" are essential during pregnancy and are of the highest available potency and to discontinue various similar misrepresentations about others of its products. In April 1937 a district federal court had declared that certain of the Vegetate products were fraudulently represented to be "health builders" and to cure various disorders. These included "BF 1," "Formula H T C No. A 45" (for arthritis), "Formula H T C No. D 44" (for diabetes), "Formula H T C No. A 417" (for hay fever and asthma) and "Formula H T C No. H 410" (for high blood pressure).

Williams Foot Preparations—In January 1941 the Federal Trade Commission reported that William Newman, trading as Newman Products Company and The Newman Institute, Brooklyn, had promised to cease representing that his "Williams Korn-X," "Williams Foot Balm," "Williams Foot Shampoo" and "Williams Foot Powder" are competent remedies for athlete's foot, swollen ankles, ingrown toenails, corns, warts and other foot troubles or that the use of these products would alleviate headaches, backaches or fatigue.

Z'Out—This product, also known as "Dr. Frohlich's Z'Out Hair Destroyer," has back of it a Louis B. Frohlich, trading as the Frohlich Laboratories, and a David F. Griff, doing business as Frohlich Distributing Company, all of Seattle. In April 1941 they promised the Federal Trade Commission to cease representing that the product will permanently destroy hair, prevent the regrowth of hair or bring about the permanent removal of hair, that it possesses any marvelous qualities or that its development is the result of seven years' work or of any amount of work, effort, experimentation or research greater than that actually used or performed in its development. In recent years the Frohlich concern has sent out a report, attributed to a Seattle chemical laboratory, to the effect that the powder form of "Z'Out" seems to depend, for its action, on strontium sulfide.

Fairystone—Ray G. Maloney, trading as Fairystone Manufacturing Company, and Willard J. Dungan and Arthur E. Maloney, doing business as Fairystone Distributing Company, all of Detroit, promised the Federal Trade Commission in April 1941 to cease representing that the "Fairystone" is an "absolute sunburn protection" which filters out the burning or ultraviolet rays of the sun and permits other sun rays to burn or tan the skin or that it will effectively conceal scars, birth marks or other cutaneous blemishes, or cause those who use it to look years younger, or will prove a competent remedy for pimples or blotched skin.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

ANNUAL CONGRESS ON MEDICAL EDUCATION AND LICENSURE
CHICAGO, Feb. 16-17, 1942. Council on Medical Education and Hospitals, Sec., Dr. William D. Cutter, 535 North Dearborn Street, Chicago.

MEDICAL CORPS, UNITED STATES NAVY

Examination. Assistant Surgeon with the permanent rank of Lieutenant (junior grade) and Acting Assistant Surgeon with the probationary rank of Lieutenant (junior grade), Jan. 5-9. Examination will be held at the Naval Hospitals at Chelsea, Mass., Newport, R. I., Brooklyn, Philadelphia, Norfolk, Va., Charleston, S. C., Pensacola, Fla., Corpus Christi, Tex., San Diego and Mare Island, Calif., Puget Sound, Wash., Great Lakes, Ill., Pearl Harbor, T. H., and Naval Medical Center, Washington, D. C. Apply Bureau of Medicine and Surgery, Navy Department, Washington, D. C.

BOARDS OF MEDICAL EXAMINERS
BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Examinations of boards of medical examiners and boards of examiners in the basic sciences were published in THE JOURNAL, January 3, page 76.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: Parts I and II. Various centers, Feb. 9-11. Exec. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia.

EXAMINING BOARDS IN SPECIALTIES

AMERICAN BOARD OF INTERNAL MEDICINE: Oral. April in advance of the meeting of the American College of Physicians and June, in advance of the meeting of the American Medical Association. Applications should be on file 6 weeks in advance of the date of oral examination. Sec., Dr. William S. Middleton, 1301 University Ave., Madison, Wis.

AMERICAN BOARD OF NEUROLOGICAL SURGERY: New York, June. Sec., Dr. R. Glen Spurling, 404 Brown Bldg., Louisville.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: Oral. Part II. Groups A and B Atlantic City, May or June. Final date for filing application is March 1. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh.

AMERICAN BOARD OF OTOLARYNGOLOGY: Oral and Written. All Groups. Philadelphia, June, preceding the meeting of the American Medical Association. Final date for filing application is March 1. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha, Neb.

AMERICAN BOARD OF PATHOLOGY: St. Louis, March 30-31. Final date for filing application is Jan. 30. Sec., Dr. F. W. Hartman, Henry Ford Hospital, Detroit.

AMERICAN BOARD OF PEDIATRICS: Oral. Cleveland, May 13, preceding the Region III meeting of the American Academy of Pediatrics. Written. Locally, February 14. Sec., Dr. C. A. Aldrich, 707 Fullerton Ave., Chicago.

AMERICAN BOARD OF RADIOLOGY: Oral. All Groups. Atlantic City, June 4. Final date for filing application is April 1. Sec., Dr. Byrl R. Kirklin, 102-110 Second Ave., S. W., Rochester, Minn.

AMERICAN BOARD OF SURGERY: Written. Part I. Various centers, March 2. Sec., Dr. J. Stewart Rodman, 225 S. Fifteenth St., Philadelphia.

District of Columbia Reciprocity Report

The District of Columbia Commission on Licensure reports 27 physicians licensed to practice medicine by reciprocity from June 10 through September 19. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
University of California Medical School.....	(1937)		California
University of Southern California School of Medicine..	(1938)		California
George Washington University School of Medicine....	(1931)		California,
(1937) Pennsylvania			
Georgetown University School of Medicine.....			New Jersey
Howard University College of Medicine.....			Virginia
Indiana University School of Medicine.....			Indiana
Louisville Medical College.....	(1906)		Mississippi
University of Louisville Medical Department.....	(1910)		Texas
University of Maryland School of Medicine and College of Physicians and Surgeons.....	(1937), (1939)		Maryland
Detroit College of Medicine and Surgery.....	(1933)		Michigan
Columbia University College of Physicians and Surgeons.....	(1927)		New York
Cornell University Medical College.....	(1937)		New York
Long Island College of Medicine.....	(1938)		Penna.
New York University College of Medicine.....	(1936)		New York
University of Cincinnati College of Medicine.....	(1933)		Ohio
Hahnemann Medical College and Hospital of Philadelphia.....	(1937), (1938)		Penna.
Jefferson Medical College of Philadelphia.....	(1938)		Penna.
Temple University School of Medicine.....	(1938)		Penna.
Medical College of the State of South Carolina.....	(1935)		S. Carolina
Meharry Medical College.....	(1939)		Tennessee
University of Tennessee College of Medicine.....	(1939)		Arkansas
Vanderbilt University School of Medicine.....	(1915)		Tennessee
University of St. Andrews Conjoint Medical School..	(1936)		New York
Osteopath *			Michigan

* Licensed to practice surgery.

Oregon October Report

The Oregon State Board of Medical Examiners reports 10 physicians licensed to practice medicine by reciprocity and 1 physician so licensed on endorsement of credentials of the National Board of Medical Examiners from September 20 through October 16. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Stanford University School of Medicine.....	(1939)		California
University of Colorado School of Medicine.....	(1939)		Colorado
Northwestern University Medical School.....	(1924)		Nebraska
University of Louisville School of Medicine.....	(1940)		Kentucky
St. Louis University School of Medicine.....	(1925)		Nevada,
(1939) Missouri			
New York Homeopathic Medical College and Flower Hospital	(1935)		New York
University of Oklahoma School of Medicine.....	(1937)		Kansas
University of Oregon Medical School.....	(1940)		California
Osteopath *			Nebraska

School	LICENSED BY ENDORSEMENT	Year Grad.
Johns Hopkins University School of Medicine.....	(1934)	

* Licensed to practice surgery.

South Carolina November Report

The State Board of Medical Examiners of South Carolina reports the oral and written examination for medical licensure held at Columbia, Nov. 10-11, 1941. The examination covered 17 subjects and included 39 questions. An average of 75 per cent was required to pass. Three candidates were examined, all of whom passed. Nine physicians were licensed to practice medicine by reciprocity. The following schools were represented:

School	PASSED	Year Grad.	Number Passed
University of Louisville School of Medicine.....	(1937)		1
Medical College of the State of South Carolina.....	(1941, 2)		2

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Emory University School of Medicine.....			Georgia
University of Louisville School of Medicine.....			Kentucky
University of Maryland School of Medicine.....	(1929)		Maryland
of Physicians and Surgeons.....	(1929), (1940, 3)		Tennessee
Meharry Medical College.....	(1929), (1940, 3)		Tennessee
University of Virginia Department of Medicine.....	(1936)		N. Carolina,
(1937) Virginia			

Wyoming October Report

The Wyoming State Board of Medical Examiners reports the written examination held at Cheyenne, Oct. 6, 1941. Five candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad.	Number Passed
College of Medical Evangelists.....	(1941)		1
Louisville Medical College.....	(1902)		1
University of Louisville School of Medicine.....	(1940)		1
University of Oklahoma School of Medicine.....	(1939)		1
University of Pennsylvania School of Medicine.....	(1938)		1

District of Columbia November Report

The District of Columbia Board of Examiners in Medicine and Osteopathy reports the written examination for medical licensure held in Washington, Nov. 10-12, 1941. The examination covered 9 subjects and included 60 questions. An average of 75 per cent was required to pass. Ten candidates were examined, all of whom passed. Twenty-one physicians were licensed to practice medicine on endorsement of credentials of the National Board of Medical Examiners. The following schools were represented:

School	PASSED	Year Grad.	Number Passed
George Washington University School of Medicine.....	(1939), (1940, 3)		4
Georgetown University School of Medicine.....	(1938), (1939), (1940)		3
Howard University College of Medicine.....	(1940, 2)		2
Rush Medical College.....	(1922)		1

School	LICENSED BY ENDORSEMENT	Year Grad.
George Washington University School of Medicine.....	(1939, 2), (1940)	
Georgetown University School of Medicine.....	(1937), (1938), (1939, 2), (1940, 7)	
Rush Medical College.....	(1932)	
Johns Hopkins University School of Medicine.....	(1933)	
Harvard Medical School.....	(1937)	
Tufts College Medical School.....	(1937)

Duke University School of Medicine.....	(1939)	
University of Oregon Medical School.....	(1929)	

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Medical Practice Acts: Right of Board of Medical Examiners to Revoke License of Naturopath; Right of Naturopaths to Prescribe Drugs.—The plaintiff, Henry Gross, obtained a certificate issued by the board of examiners of the Association of Naturopaths of California and, on the purported authority of that certificate, commenced the practice of naturopathy in the city of Los Angeles. In 1909 a statute was enacted which provided that persons who held "an unrevoked certificate" issued by the Naturopathic Association and who had practiced naturopathy prior to the passage of the 1909 act were authorized to continue such practice and entitled to have such certificate endorsed by the board of medical examiners. This act also provided:

But all certificates herein mentioned may be revoked for any unprofessional conduct, in the same manner and upon the same grounds as if they had been issued under this act.

In 1913 the existing medical practice act was repealed and a new one enacted under which persons desiring to practice naturopathy could secure drugless practitioners' certificates from the board of medical examiners. In 1937 the medical practice act was codified and became a part of the Business and Professions Code. Subsequently the plaintiff was charged with a violation of the Business and Professions Code in that he administered and prescribed drugs to his patients. The board of medical examiners found him guilty and placed him on probation for three years. Accordingly the plaintiff filed a petition for a writ of mandate directing the board to dismiss the charges which had been filed against him and restraining the board from preventing the plaintiff from prescribing for his patients. From a judgment sustaining the board's demurrer and dismissing the plaintiff's petition, the plaintiff appealed to the district court of appeal, second district, division 2, California.

The plaintiff first contended that the board of medical examiners had no jurisdiction over him because all of the statutory provisions relating to naturopaths were eliminated from the 1913 law creating the respondent board. The district court of appeal said that the legislature, by comprehensive enactments, intended to regulate all persons engaged in any of the various healing arts. When the plaintiff's certificate was endorsed pursuant to the provisions of the 1909 act, the effect was the same as if the board of medical examiners had actually issued a new license. Furthermore, the 1909 act specifically authorized disciplinary proceedings against the holders of such endorsed certificates. The court therefore held that the board had jurisdiction over the plaintiff and that it would be unreasonable to conclude that all practitioners of the healing art were subject to regulation except those who were practicing naturopathy in 1909.

The plaintiff also contended that he did not perform any acts not permitted by his naturopathic certificate. The laws of California did not define naturopathy but the articles of incorporation of the Association of Naturopaths provided that its members were authorized to treat patients by the use of "herbs" and other specifically named agencies. The evidence showed that, for at least one of his patients, the plaintiff prescribed a substance known as Alpha Naphco, which bore the following matter on its label, as read into the record by the Deputy Attorney General:

Alpha Naphco, formerly Benetol. Activity—(spelling) Phen. cocf.—I imagine that is "coefficient." (continuing reading): "—H. L. Test 1.46. Phenol coefficient against yellow pus germs in 1/2 blood serum 1/2 saliva at body heat 3.11. Inert Ingredient—Ined.—" It reads here—(continuing reading): "Glycerine 32%, Water 40%. Contents—Not less than six ounces liquid. Carrel Laboratories, Redondo Beach, California, Formerly Benetol Products Co."

He also prescribed a beef extract which was not composed of herbs in their natural form. Expert testimony, said the court, was not needed to show that the prescription of capsules of grayish powder and a liquid with a large content of glycerin could not be classified as the use of herbs. The district court

of appeal therefore held that the evidence was sufficient to sustain a finding that the defendant had prescribed substances which were a part of materia medica and could not be classified as "herbs." The action of the board was therefore sustained.—*Gross v. Molony*, 102 P. (2d) 816 (Calif., 1940).

Contracts: Validity of Agreements in Restraint of Professional Practice.—The plaintiff and the defendant formed a partnership for the practice of medicine in Lumberton, N. C. The agreement provided for the dissolution of the partnership on ninety days' written notice and contained a provision under which the defendant agreed not to engage in the practice of medicine in Lumberton, or within 100 miles thereof, for a period of five years following the dissolution of the partnership. Later the partnership was dissolved and thereafter the defendant opened an office in Lumberton for the practice of medicine. The plaintiff brought suit to enjoin the defendant from practicing medicine contrary to the partnership agreement and, from an order granting a restraining order and continuing it until final hearing, the defendant appealed to the Supreme Court of North Carolina.

The plaintiff contended that the contract was clear and unambiguous and freely entered into; the defendant contended that it was void because contrary to public policy. The Supreme Court said that, actually, public policy is concerned with both sides of the question; it favors the enforcement of contracts intended to protect legitimate interests and frowns on unreasonable restrictions. In the opinion of the court it is as much a matter of public concern to see that valid contracts are observed as it is to frustrate oppressive ones. The determinative factor is the reasonableness of the agreement. The Court found that both of the parties regarded the restriction as reasonable when they signed the agreement and that both were familiar with the situation. The defendant himself had insisted that an agreement be signed, and he did not then object to the restrictive covenant. Both parties felt, at the time the agreement was executed, that the plaintiff had a legitimate interest to protect, and the restriction itself was reasonably limited as to both time and place. The Supreme Court therefore held that the defendant was bound by his agreement and could not, looking at it retrospectively, regard it as unwise and seek to void it on grounds of public policy. The contract was not forbidden by any principle of policy or law. The defendant could be as useful to the public at any other town as he could at Lumberton, and the lives and health of persons in other villages were just as important. Communities therefore were not injured, concluded the Court, by a stipulation of this kind between two physicians. The restraining order was affirmed.—*Beam v. Rutledge*, 9 S. E. (2d) 476 (N. C., 1940).

Chiropractors: License as Prerequisite to Collection of Fees.—In this case the court of civil appeals of Texas denied relief to a chiropractor who had sued a patient to recover compensation for services rendered. The chiropractor had no license to practice in Texas and the court held that, since he had no legal right to perform the services, he could not lawfully make and collect a charge therefor.—*Park v. Coulson*, 139 S. W. (2d) 667 (Texas, 1940).

Society Proceedings

COMING MEETINGS

Annual Congress on Industrial Health, Chicago, Jan. 12-13. Dr. C. M. Peterson, 535 North Dearborn St., Chicago, Secretary.
Annual Congress on Medical Education and Licensure, Chicago, Feb. 16-17. Dr. William D. Cutter, 535 North Dearborn St., Chicago, Secretary.

American Academy of Orthopedic Surgeons, Atlantic City, N. J., Jan. 11-15. Dr. Rexford L. Diveley, 1103 Grand Ave., Kansas City, Mo., Secretary.

American Orthopsychiatric Association, Detroit, Feb. 19-21. Dr. Norvelle C. LaMar, 149 East 73d St., New York, Secretary.
Central Surgical Association, Chicago, Feb. 27-28. Dr. George M. Curtis, Ohio State University, Columbus, Ohio, Secretary.
Pacific Coast Surgical Association, San Francisco and Del Monte, Calif., Feb. 17-20. Dr. F. L. Reichert, Stanford University Hospital, San Francisco, Secretary.
Society of Surgeons of New Jersey, Trenton, Jan. 23. Dr. Walter R. Mount, 21 Plymouth St., Montclair, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1931 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Heart Journal, St. Louis

22:439-582 (Oct.) 1941

- *Rheumatic Infection in Childhood: Influence of Type of Onset and Calendar Year of Onset. Rachel Ash, Philadelphia.—p. 439.
- Further Observations on Mechanism of Production of Short PR Interval in Association with Prolongation of QRS Complex. C. C. Wolfert and F. C. Wood, Philadelphia.—p. 450.
- *Arteriosclerotic Aneurysms and Senile Ectasia of Thoracic Aorta. M. deG. Ruffin, B. Castleman and P. D. White, Boston.—p. 458.

- Effect of Abrasion of Surface of Heart on Inter coronary Communications. E. J. Stanton, P. Schildt and C. S. Beck, Cleveland.—p. 529.
- The Coronary Operation. C. S. Beck, Cleveland.—p. 539.
- Sympathectomy and Experimental Occlusion of Coronary Artery. A. Yodice, Buenos Aires, Argentina.—p. 545.

Rheumatic Infection in Childhood.—Ash made a follow-up study of 583 children whose rheumatic infection had occurred during 1922 to 1936, inclusive, and who were cared for at the Children's Hospital. In 1939, 527, or 90.4 per cent, of these children were traced. Twenty-six of the untraced children had been followed previously for three to thirteen years; thus the average follow-up period for 553 rheumatic children was nine and six-tenths years. At the end of this time, 64.2 per cent had signs of valvular heart disease and 21.7 per cent had died of rheumatic infection. An additional 3.5 per cent had died of bacterial endocarditis or another associated infection. The prognosis of acute carditis was most grave and that of chorea most favorable. Children with a diagnosis of potential heart disease at the onset frequently tended to remain free of signs of heart disease. The severity of the rheumatic infection tended to decrease during the period of observation, especially among patients whose primary symptoms were arthritic. The improvement could not be ascribed to racial variation, changes in type of onset, progressive decline in recurrences or a modification in the admission policy of the hospital. It is undetermined whether the intensive supervision of the child from the first manifestation of the disease has had any effect on the natural trend to improvement. The recently adopted conservative attitude toward tonsillectomy has had no unfavorable influence. Transference to a convalescent home, although insuring stabilization of the infection, is no substitute for absolute bed rest for the child with any degree of active infection. Part, if not all, of the improvement would seem to be due to a spontaneous change in the character of the disease. In spite of the seeming decline in severity, rheumatic infection remains the most serious disease which attacks children past infancy.

Arteriosclerotic Aneurysms and Ectasia.—Ruffin and his co-workers were prompted by the death from internal hemorrhage, caused by rupture of the thoracic aorta, of 2 old women with nonsyphilitic thoracic aortic aneurysms to survey the literature and to analyze the postmortem records of the Massachusetts General Hospital. Their first case was one of arteriosclerotic aneurysm and the second one of dissecting aneurysm in an aorta which was the seat of senile ectasia. Of the 9,600 cases in which necropsy was performed at the hospital since 1897 aneurysm was observed in 116; 17 were cases of true dissecting aneurysm with medionecrosis aortae cystica, in 13 cases small "dissections" had occurred mostly in and about small atherosclerotic plaques and of the 86 remaining cases the aneurysms in 21 were in the ascending aorta, in 37 mainly in

the arch, in 8 in the descending thoracic portions and in 20 in the abdominal aorta. Of the 66 cases of thoracic aneurysm, the disorder in 60 was syphilitic and in 3 arteriosclerotic, and in 3 there was considerable dilatation of the ascending aorta without arteriosclerosis—a condition that the authors term "senile ectasia." Of the 20 abdominal aortic aneurysms, 3 were syphilitic and 17 were arteriosclerotic; all of the former and 6 of the latter ruptured. The average age at death of the patients with syphilitic aneurysms was 46.4 years, and of those with arteriosclerotic aneurysms and senile ectasia it was 72.7 years. From the authors' cases it is to be realized that even large thoracic aortic aneurysms may be of an arteriosclerotic or senile nature and that they too may rupture, with fatal hemorrhage. Important clues to the diagnosis of an arteriosclerotic aneurysm and senile ectasia of the thoracic aorta, in some cases at least, are old age, female sex and a negative serologic reaction. The authors conclude that in the future, as a result of a constantly aging population and a gradual reduction of syphilis among the masses, these conditions will be found more often.

Esophageal Electrocardiogram and Myocardial Infarction.—Nyboer studied the standard lead, the selected precordial lead (4) and the selected esophageal lead from the ventricular and auricular levels of 4 normal subjects, of 1 patient with anterior myocardial infarction, of 10 with posterior myocardial infarction and of 10 with a history and/or physical signs suggestive of myocardial disease. The esophageal electrocardiogram from the ventricles was as specifically diagnostic of posterior myocardial infarction as the precordial electrocardiogram is diagnostic of infarction of the anterior wall. The criteria for a diagnosis of posterior myocardial infarction by the esophageal ventricular lead are essentially the same as those for a diagnosis of anterior myocardial infarction by the precordial lead.

Therapy in Angina Pectoris.—Freedberg and his collaborators determined the pharmacodynamic action of drugs on 15 patients with angina pectoris repeatedly mounting and descending a two step stairway. The administration of glyceryl trinitrate, theobromine with sodium acetate or quinidine sulfate enabled some patients to do a measurably greater amount of work under standardized conditions and, at the same time, prevented the changes in the ST segment which result from exercise. Inert drugs had no such effect. Digitalis was given to the patients and in some it increased the frequency of attacks in daily life, decreased the amount of work which could be performed under standardized conditions, increased the electrocardiographic changes following exertion and produced electrocardiographic changes similar to those observed after exercise without medication.

Treatment of Angina Pectoris.—According to Freedberg and his collaborators, the inhaling of octyl nitrite by patients with angina pectoris was effective in preventing attacks on exertion and in shortening the duration of such attacks. Its action is similar to that of glyceryl trinitrate and amyl nitrite. Inhalation of octyl nitrite permits more rapid absorption but makes accurate dosage impossible. The commercial inhalers now available are not satisfactory. Dose for dose, octyl nitrite is much more costly than glyceryl trinitrate but less so than amyl nitrite.

Congenital Heart Disease as Cause of Sudden Death.—According to Levinson, in the Cook County Hospital during the years 1929 through 1939 necropsy was performed on 12,837 infants, children and adults. There were 78 cases, or 0.607 per

cent, of congenital heart disease in children of 1 year or less. In 35 of the 78 cases the disease was diagnosed clinically, whereas in 43 there was no previous history or clinical evidence of congenital disease of the heart or of the blood vessels. Of 1,921 cases in which necropsy was done in the Research and Educational Hospitals from the years 1927 through 1939 there was gross and definite evidence of congenital heart disease in 23. Of 8,500 cases investigated by the author as coroner's physician during the last thirteen years, 50 per cent, or 4,250, were instances of sudden or unexpected death; that is, the persons died without having been previously ill or without having been under a physician's care. In this group there were 8 cases in which children less than 1 year of age had congenital defects of the heart or of the blood vessels directly responsible for the unexpected death. When questioned the parents of the 8 children stated that the children had not been sick at any previous time. Some of the children had been taken to the Infant Welfare Station, and their mothers had not been warned of any evidence of illness.

Factors in Appendicitis Mortality.—Mulsow studied 122 patients who died from appendicitis in Cedar Rapids during the last ten years. He found that the morbid anatomy of the appendix was the most important factor in the death of 41 of the 122. Only 12 of the 41 gave a history of taking laxatives; they were not in the extreme ages of life and they were seen within forty-eight hours by a surgeon. All but 5 were operated on. One of the 5 was treated by Christian science and 2 by chiropractic measures. At the necropsy of these 3 patients, a gangrenous ruptured appendix, with general peritonitis, was observed. The fourth of the 5 patients was a woman of 35 with a badly deformed spine and chest, in whom the diagnosis was uncertain during life, but at necropsy a ruptured appendix, with peritonitis, was observed. The fifth patient, a woman of 46 with rheumatic heart disease, was regarded as a poor surgical risk. Of the one hundred and twenty-two appendixes twenty-five were in the retrocecal position, thirty-nine had concretions in the lumen and one had a diverticulum. Seventeen, or about 13 per cent, of the deaths followed the removal of a noninflamed appendix. Six of the 17 deaths were due to peritonitis, 3 to pneumonia, 2 each to paralytic ileus and embolism and 1 each to anesthesia, septicemia, coronary occlusion and surgical shock. Concretions in the lumen or kinks in the appendix make acute appendicitis a dangerous disease. Concretions were found in three fourths of the perforated appendixes and in half of the gangrenous ones. Fourteen of the patients who died of a ruptured appendix had a history of a previous attack, and because of the previous recovery they delayed in calling a surgeon. Before the age of 15 there were twice as many deaths of girls as of boys, between 15 and 50 twice as many men as women died and after 50 the number of deaths was about equal for the two sexes.

Effect of Urine Extracts on Peptic Ulcer.—Sandweiss and his collaborators point out that from 1 to 5 mg. of extract of pregnancy urine and normal female urine benefited experimental ulcers in Mann-Williamson dogs in the presence of an essentially unaltered gastric acid juice. The beneficial effect was due to the stimulation of fibroblastic and epithelial proliferation and the formation of new blood vessels. Urine con-

tains a gastric secretory depressant. Therapy with the present available extract has shown encouraging results in 63 patients with chronic duodenal ulcer. Treatment did not prevent recurrences. While the number of relapses within six months and one year was approximately the same as obtained in similar patients treated with diet and alkalis, the patients treated with urine extract enjoyed a more liberal diet. While the patients treated with other parenteral products also enjoyed a more liberal diet, fewer of these patients became symptom free during treatment and more of them had relapses within six months and one year as compared with the patients treated with urine extract. It is probable that diet, alkalis and urine extract might produce even better results. In view of the encouraging experimental and clinical results the authors are carrying out further clinical studies with larger doses of a more highly concentrated urine extract.

Cerebral Embolism in Mitral Stenosis.—Harris and Levine tried to determine why a sudden cerebral embolism developed in 46 patients with mitral stenosis from the Peter Bent Brigham Hospital and 24 from private practice while they were in a fair state of cardiac compensation. Auricular fibrillation was present in 55 patients, and in only 3 of them was it transient. The average duration of the fibrillation was twenty-two months; the range was from three days to nine years. It appears that the cerebral accident is apt to occur during the early weeks or months after the onset of persistent auricular fibrillation. In 5 patients, after the fibrillating state reverted to a normal rhythm either spontaneously or after quinidine therapy embolism took place within a few hours or a day or two. In 17 with regular rhythm at the time of the cerebral accident fibrillation of the auricles, as far as could be ascertained, had not been present previously. The "immediate mortality" (24 deaths) and the survival period of those recovering from embolism were not influenced by auricular fibrillation, despite the fact that hypertension and congestive failure were more common in this group. There were 23 with and 49 without congestive heart failure; the "immediate mortality" for the former was 53 per cent, and for the latter it was 24 per cent. The 4 patients with congestive failure with regular rhythm died "immediately," while only 4 of 13 with regular rhythm but without failure died "immediately." It seems that cerebral embolism is more likely to occur in patients with mitral stenosis having little objective evidence of congestive heart failure than it is in those with advanced failure who are bedridden. It occurs more frequently in compensated than in decompensated mitral stenosis because the former state lasts longer.

Sensory and Motor Centers in Hypothyroidism.—Enzer and his associates determined the state of the sensory and motor centers of 13 patients with a decreased metabolic rate and hypothyroidism by the fusion frequency of flicker and finger movements. The sensory and the motor centers were deteriorated in these patients. In some patients the decrease of fusion frequency and in others the decrease of motor frequency was more pronounced. Eleven of 13 patients had values of fusion frequency lower than the lowest value of 45 normal control subjects; the other 2 had values that coincided with the lowest normal values. This explains the disposition to increased fatigability of such

patients, as the fusion frequency of flicker is diminished in nervous fatigue. Weakness of motor centers is shown by the decrease of frequency during performance.

Plasma Creatinine Determination.—According to Arkin and his colleagues, their new simple determination of plasma creatinine provides a diagnostic procedure for detecting mild disturbances of glomerular filtration and, consequently, of renal damage of low grade. These disturbances are of diagnostic and prognostic importance in acute nephritis, chronic nephritis, nephrosis, nephrosclerosis, urologic conditions and heart failure. In extrarenal azotemia the increase of the creatinine level is relatively less substantial than that of urea and nonprotein nitrogen, apparently because of an increased reabsorption of urea. The reagents are a saturated solution of picric acid and 10 per cent chemically pure sodium hydroxide. To 12 cc. of picric acid 4 cc. of oxalated plasma is added, drop by drop. The test tube is shaken and immersed in a boiling water bath for fifteen seconds. The mixture is filtered through a no. 44 Whatman filter. To 10 cc. of the cooled filtrate 0.5 cc. of sodium hydroxide is added and the mixture is again filtered. The colored solution formed is read with monochromatic light with a filter of 530 millimicrons twenty minutes after the sodium hydroxide has been added. The determination is made with a colorimeter, a photometer or a photoelectric colorimeter. By the aid of a known creatinine solution a comparison curve is made in the range between 0.5 and 3 mg. per hundred cubic centimeters of plasma. If the creatinine concentration exceeds this range the plasma is diluted with water. The normal level lies between 0.6 and 0.95 mg. per hundred cubic centimeters of plasma. It is constant in normal persons on different days or at different times of the day, even after the ingestion of food or fluid. Any slight increase over 1 mg. per hundred cubic centimeters is a probable sign of disturbed glomerular filtration. The method has been used four hundred and seventy-four times for 278 patients with renal disturbances or diseases commonly associated with extrarenal azotemia.

Hunner Ulcer of Bladder.—Higgins employed various types of therapy for his 100 patients with Hunner ulcer, but he observed that conservative treatment, fulguration of the ulcer and overdistention of the bladder, is the best method. Foci of infection must be eradicated. Of 69 patients receiving such treatment 17 were definitely cured, 10 were lost track of, 14 were not improved and 28 were improved. Four patients also had other operative procedures; 1 of them was cured and 1 was improved.

Lime Burns of Eye.—Since the prognosis of severe burns of the eye treated conservatively (by irrigation and with atropine and ointment) has been bad, Brown used several membranes in experiments on rabbits to prevent the burned palpebral conjunctiva from being in constant contact with the corneal surface, which he found acted as a corrosive agent. He found rabbit peritoneum to be the tissue of choice. He cites 4 patients who

sustained lime burns of the eye and in whom he used rabbit peritoneum to protect the surfaces of the eye from coming in contact with the burned palpebral conjunctiva. Affected surfaces must be completely separated by smooth tissue to allow healing. A section of peritoneum about 4.5 by 10 cm., passed through three successive washes of warm physiologic solution of sodium chloride, is used. The needles of two double armed no. 5 silk sutures are passed through the center area of the tissue about 2.5 cm. apart. The needles are then passed through the upper fornix, the tissue is placed as far as possible into the upper fornix and the sutures are then tied over buttons to prevent their cutting through the skin. The tissue is smoothed out over the eye and similarly sutured in the lower fornix. Any medication or irrigation may be applied beneath either surface of the flap. The flap is removed when the cornea is healed and the palpebral conjunctiva seems quiet, that is in about two weeks. If no reaction or infection is manifest it is best to leave the flap for three weeks or longer. The flap may be replaced whenever it becomes macerated or shredded.

Causes of Blindness in Pennsylvania.—Cowan and English state that since 1934, when an act granting pensions to blind persons in Pennsylvania was enacted, the causes for the blindness of 15,676 persons or 31,352 eyes have been tabulated. Persons 21 or older with a visual acuity of 20/200 (6/60) or less were considered industrially blind. This is the definition of blindness adopted by the Committee on Statistics of the Blind. The outstanding causes in the order of frequency were senile cataract, uveitis, glaucoma, trauma, congenital anomalies and neonatal ophthalmia. Since May 1939, when therapeutic procedures have been recommended the vision of 11.1 per cent of the persons with whom contact was established has been restored or improved. This has resulted in a substantial saving to the commonwealth in the payment of pensions.

Protein Hydrolysate for Hypoproteinemia.—Beling and Lee point out that the feeding of a hydrolysate of proteins from beef, milk and wheat to 30 patients with hypoproteinemia satisfactorily replaced proteins in the plasma and corrected the various anomalies which accompanied the hypoproteinemia. Replacement was rapid but was not fast enough for the treatment of shock and immediate hypoproteinemia. The hydrolysate is valuable as an adjunct to intravenously administered plasma. Its preoperative and postoperative use is important in correcting hypoproteinemia before and in preventing its occurrence after gastrointestinal surgical procedures.

Carcinoma of Upper Extremity.—Campbell believes that carcinomas of the upper extremity, although not frequent, are too often underrated, overlooked or undertreated. A good prognosis is to be expected only if early treatment is vigorous. Among the 36 cases patients with the disease observed at the hospital of the University of Michigan 32 were men and 4 were women. At the initial examination, 44.4 per cent of the patients had palpable epitrochlear or axillary nodes or both, and 50 per cent suffered a recurrence or ultimately died of the carcinoma. Only 4 patients have lived five years or more without a recurrence. However, many of the patients died of intercurrent disease, without evidence of recurrence, before the five year limit was reached. In 18 patients proved unrelated cutaneous

neoplasms were present; fourteen were on the face and four on other extremities. Thirty-four of the carcinomas were of the squamous cell type, one was mediocellular and one was an adenocarcinoma of sweat gland origin. Operation and roentgen or radium irradiation remain the most popular procedures in the treatment of the local lesions and the involved lymph nodes. Although 15 of the 36 patients died, 7 died from causes attributed to the carcinoma and 8 from intercurrent disease. The average age of those dying from cancer was 52.7 years, and of those dying from intercurrent disease it was 75 years.

Gastrojejunocolic Fistula.—From a study of the 49 patients with gastrojejunocolic fistula operated on at the Mayo Clinic from 1930 to 1939 Gray and Sharpe conclude that the prohibitive mortality rate following one stage reparative procedures can be lowered materially by adequate preoperative management. Eighteen of the 49 patients died; of 13 receiving no preoperative preparation 8 died, and of 36 given fairly satisfactory preparation 10 died. However, only 1 of 7 having careful and adequate preoperative attention died.

Studies on Sulfadiazine.—Long and his colleagues after finding sulfadiazine effective in controlling experimental pneumococci, staphylococci and hemolytic streptococci infections used it clinically for 230 patients with bacterial infections, including 105 with pneumonia. As relatively high concentrations of sulfadiazine can be maintained in the blood without frequent toxic reactions, the therapeutic result is better with this drug than it is with other sulfanilamide derivatives. For the mild or moderately severe hemolytic streptococci infections (tonsillitis, erysipelas, otitis media, mild scarlet fever and the like) the authors prefer oral therapy. They base the initial dose on 0.05 Gm. per kilogram of body weight. Two of 3 patients ill with meningococci meningitis responded favorably to the drug, while the other died within one hour after therapy was started. Of 6 patients with subacute bacterial endocarditis, 1 has made a dramatic response to therapy and the other 5 were not materially improved by chemotherapy. Five of the 12 patients with various types of staphylococci infections (osteomyelitis) who were given sufficient doses of the drug to maintain a level in the blood of 5 to 7 mg. made a gratifying response to therapy, and all continued to take the drug for at least four months. From July 1940 to June 1941 105 adults with pneumonia have been treated with sulfadiazine alone or with sulfadiazine and type specific antipneumococcus serum. Of the 75 patients who received only sulfadiazine 56 had pneumonia due to pneumococci of types I to VIII, 7 had bacteremia, 8 had complications associated with the pneumonia and 14 had a major concurrent disease. Only 1 patient died, nine hours after entering the hospital. The response to sulfadiazine therapy was usually prompt, but it did depend, at least in part, on the concentration of sulfadiazine in the blood during the first twelve to twenty-four hours of treatment. Of the 30 patients with pneumococci pneumonia treated with sulfadiazine and antipneumococcus serum 16 had positive blood cultures and 18 had major concurrent diseases. Seven patients died, of whom 6 had major concurrent diseases and 4 were in shock when admitted to the hospital. Only 17 of the 230 patients treated experienced toxic reactions.

Ligation of Great Cardiac Vein for Angina Pectoris.—Their experimental observations on dogs suggested to Fauteux and Palmer that venous ligation would be of considerable value in the treatment of advanced coronary disease in man. Consequently, on April 19, 1939, they operated on a patient with severe angina of effort. More than two years have elapsed since the operation, and the patient has been entirely free from pain. This relief the authors believe is due to an improvement in the coronary circulation rather than to any interruption of nervous pathways or danger signals. It is their opinion that at least for the present only patients with severe angina pectoris who have not responded to medical treatment should be operated on. In other words, until further experience is gained venous ligation should be reserved for angina pectoris of atheromatous origin rather than for coronary disease as such.

Immunization of Canadian Air Force.—Sellers states that outbreaks of diphtheria and scarlet fever among the air force personnel during the winter and spring of 1940-1941 caused procedures promising effective future control to be introduced. The program calls for Schick and Dick testing and subsequent immunization of all air force personnel throughout Canada and Newfoundland during the training period, before proceeding overseas where these diseases are more prevalent. By this procedure it can be expected that diphtheria will be almost completely eliminated from the air force personnel. For scarlet fever the ground is not so certain, but immunization is the best available weapon. All personnel either in or entering the service are Schick and Dick tested. The result of the Schick test is read in twenty-four or forty-eight hours, and if negative it is read again in five or seven days. All personnel with positive Schick reactions (on the first or the second reading) are given subcutaneously two 1 cc. doses, four weeks apart, of alum precipitated diphtheria toxoid. Schick-sensitive persons are not given toxoid. The Dick reaction is read in twenty-two or twenty-four hours, and all those showing a positive one are given five 1 cc. injections of scarlet fever toxin subcutaneously at weekly intervals in graded doses. Special clinics with trained personnel have been set up at large stations of initial entry. Permanent records of all tests and inoculations are made, and when immunization is complete the records are sent to air force headquarters to be used for statistical purposes.

Anuria.—McClelland discusses three types of anuria: anuria from sulapyridine, from calculi on both sides and from crush injury in mines. Treatment must be directed at the cause. An obstructing calculus must be removed. If both ureters are blocked it is sufficient to remove the stone or stones from one side and to treat the other side expectantly. The one well functioning kidney is sufficient to sustain life and to bring the nitrogen content of the blood down to normal, and the obstruction of the other side can be treated when the patient's condition is improved. Hence it is the author's belief that unilateral anuria must occur more frequently than it is realized. The

shutting off of one kidney is evidently not important as long as the function of the other kidney is good. Ureteral obstruction due to sulfapyridine crystals can be overcome by the passage of ureteral catheters. Surgical intervention is indicated only if ureteral catheterization fails. There is no specific treatment for crush injuries. The intravenous administration of saline and dextrose solutions or dextrose in distilled water is useful. The dextrose should be made up in distilled water if the patient's nonprotein nitrogen level is more than 100 mg. Aminophyllin and caffeine with sodium benzoate should be used.

Gradation of Ewing's Tumor.—In studying the cellular activity of thirty Ewing tumors Campbell and Hamilton tried to divide them into grades, according to the number of mitotic figures observed in a high power field: grade 1, one to five figures; grade 2, six to ten figures, and grade 3, eleven to fifteen figures. It appears to the authors that a patient with a tumor having five or less mitotic figures has approximately a 23 per cent chance to survive ten years and a 31 per cent chance to live five years, whereas if the count is eleven or more he will

probably not live for much longer than one year. None of the authors' patients with grade 2 tumors lived ten years, but 3, or 33 per cent, lived more than five years. Roentgenograms of the thirty tumors indicate that the early stage of the tumor, characterized by osseous condensation, is concomitant with increased cellular activity, whereas late osseous changes are usually accompanied by diminished cellular activity. Studies of large numbers of cases might throw more light on the subject and lead to the discovery of a method of establishing a more accurate prognosis.

Fractures of Tibia in Adults.—Hudack compared the operative and nonoperative treatment of eighty-two tibial fractures in adults treated from 1929 to 1938. He found that operative treatment gave assurance of a surer course and better results than did nonoperative treatment.

Conservative Treatment of Serratus Palsy.—Wolf describes a brace for patients with permanent paralysis of the serratus muscle that allows complete use of the arm, presses the winged scapula in its normal position against the wall of the chest and prevents scapular rotation.

*Treatment of Recurrent and Threatened Abortion: Report of 226 Cases. J. Kotz, Elizabeth Parker and M. S. Kaufman, Washington, D. C.—p. 838.

Relation of Estrogen to Nausea and Vomiting.—Greene and Dorr present evidence that there is a definite relationship between the amount of diethylstilbestrol administered and the incidence of nausea and vomiting. They gave 283 women in the menopause diethylstilbestrol and related stilbene derivatives orally or parenterally. Reactions were more frequent with larger doses. The incidence of reactions was high with diethylstilbestrol, which is relatively rapidly absorbed from the site of injection. Reactions were less frequent with stilbestrol dipropionate, which is relatively slowly absorbed. Giving diethylstilbestrol orally should control menopausal symptoms and should

not cause reactions if excessive amounts are avoided. If treatment is started with a daily 0.1 mg. dose, increased after one or two weeks to 0.2 mg. and then after each succeeding one or two weeks raised to 0.5, 1, 1.5 and 2 mg. until symptomatic improvement is obtained and maintained, reactions will be reduced to a minimum. Only 22.5 per cent of the authors' patients needed doses larger than 0.5 mg. None of their patients had undesirable side reactions.

Progesterone for Threatened Abortion.—Kotz and his associates used progesterone for the treatment of 181 of 226 women whose pregnancy appeared to be threatened. Forty-two women received progesterone prophylactically (36 gave a history of one or more previous unsuccessful pregnancies, and 6 had been treated for primary sterility). The bleeding of the 45 patients who received no progesterone was slight and its duration so short that treatment did not seem warranted, or the patients were seen so late that treatment was considered useless. Of the 6 patients with primary sterility, 1 bled during pregnancy but went to near term and gave birth to a viable premature infant, and the other 5 had normal full term infants with no evidence of abnormality. The 36 patients had had a total of seventy-two pregnancies terminating in the birth of 8 full term infants. Under treatment, 28 carried through to term without bleeding, 3 had some bleeding and 5 aborted. The 3 patients with some bleeding went into labor and were delivered of viable infants two or more weeks prior to the expected date of confinement. Of 184 women who bled during the first eight months of gestation 139 were given progesterone; 102 of them were delivered of viable infants, while 82 aborted. The infants of 16 of the 102 patients who gave birth to viable babies were two or more weeks premature. Among the 184 women 91, or 49.4 per cent, had their first or only episode of bleeding in the second month of pregnancy, and of these 42, or 46.1 per cent, aborted. In the third month there were 56, or 30.4 per cent, and of these 31, or 55.3 per cent, aborted. The authors suggest that probably many abortions that physicians do not know about occur in the first month of pregnancy, as the women do not come for medical care. They believe their data demonstrate that if progesterone is to be given prophylactically its administration should be started early, certainly in the first month, and continued at least through the third month; the dose should be increased and other precautionary measures taken at the expected time of the second, third and fourth missed menstrual periods. The danger of abortion does not disappear after the third month even though the placenta takes over the production of progesterone. The hormone imbalance persists in a few women, and the continued use of progesterone benefits these women. Patients with sterility, women who habitually abort and those who have bled during the pregnancy should have prophylactic treatment continued at least until the end of the fifth month and preferably to term. There are at least three factors, probably interactive, which may cause abortions: defective germ plasm, endocrine deficiencies and nutritional deficiencies. No amount of therapy will affect the first cause, but the second and third causes may be amenable to treatment. The problem is to recognize them and to treat patients with these deficiencies adequately.

- The Ear in Flying. J. R. Poppen, Washington, D. C.—p. 974.
- Injuries to Middle and Internal Ear.**—Grove states that the tympanic membrane may be ruptured by the direct penetration of a foreign body, by the extension of a fracture of the temporal bone and by the condensation or rarefaction of air in the external auditory canal. Traumatic ruptures not associated

with fractures of the basal part of the skull usually heal by first intention and should be treated conservatively and expectantly. If suppuration of the middle ear supervenes, time-honored methods are to be used. Suppuration of the middle ear almost always follows perforations of the drum caused by burns, and often the perforation is persistent. Suppuration rarely occurs, except when encouraged by bad management, in rupture of the drum caused by a sudden elevation of air pressure in the external canal. If fracture of the temporal bone is followed by a discharge of blood or cerebrospinal fluid from the ear, nothing should be done except to place sterile cotton in the meatus and to cover the ear with sterile dressings. After a few days, if the bleeding persists, the sterile dressings should be changed. The ear should never be cleansed in less than two or three weeks and then should be cleansed mechanically with sterile instruments. Even at this date the ear should not be irrigated, because the tympanic membrane may still be perforated. If the sigmoid sinus has been injured it should be exposed and then blocked. When a fracture of the basal part of the skull exists, its treatment is of first importance. Of the three stages (shock, increasing intracranial pressure and medullary failure) to be recognized and treated in patients with severe injuries of the head the treatment of the shock should take precedence. The indications for operation are compound fractures of the skull or fractures which involve noticeable depression, extradural hemorrhage, increased intracranial pressure not improving under medical treatment and definite local paralysis or convulsions. Medical treatment consists of (1) absolute rest in bed for three to six weeks, (2) elevation of the head and trunk, (3) administration of drugs (caffeine with sodium benzoate to lower intracranial pressure and bromides and barbiturates to control restlessness), (4) dehydration (with the giving of magnesium sulfate, the intravenous administration of hypertonic solutions of sucrose or dextrose and the limitation of the fluid intake) and (5) repeated lumbar punctures to lower intracranial pressure and to remove blood from the subarachnoid spaces. Morphine tends to increase intracranial pressure and should never be administered.

Treatment of Tetanus.—Chapman and Miller report the successful outcome of therapy in a case of severe tetanus. The original injury, in a boy of 10, occurred on an ocean beach; tetanus ensued six days later. The authors believe that the six point program of treatment employed was responsible for the recovery of the child. The six features were profound sedation, surgical removal of the focus of infection, moderate intravenous doses of tetanus antitoxin, frequent lumbar punctures, maintenance of an adequate respiratory exchange and the most intelligent and constant nursing care.

"Trigeminal Neuralgia" Following Tetanus Antitoxin.—Rosenbaum reports the occurrence of "trigeminal neuralgia" following an injection of tetanus antitoxin. The patient, a foreman in a tool and die making plant, sustained a cut on his left forearm. The wound was immediately treated, and a hypodermic injection of tetanus antitoxin was given into the deltoid region of the left arm. (The patient "argued against the injection" because of a reaction to an intra-abdominal injection of tetanus antitoxin fifteen years previously.) The day after the injection the left upper arm became swollen and painful. This subsided in about two weeks. About two days after the injection headache and severe nuchal pain developed and lasted for three weeks. A few days after the headache and nuchal pain had subsided the patient had a sudden severe attack of "shooting" pain in the left side of his face. The attack subsided after one hour. Ten days later a similar attack ensued. This attack subsided abruptly after two hours, during which time the patient was given two injections of morphine sulfate. A third, similar, attack, lasting two hours and unrelieved by morphine, occurred six days later and a fourth attack within two days more. The patient inhaled trichlorethylene during the fourth attack, without relief. The history was irrelevant except for the reaction fifteen years before. A few days after this injection large urticarial wheals developed around the site of the injection, and for about six months the anterior surface of the abdominal wall remained so painful that the patient was unable to wear a belt or fasten the upper buttons of his trousers. Ten months after the last attack of "trigeminal neuralgia" the patient has been free of attacks and in perfect health. The close association between the "attacks" and the "meningitic" reaction (headache and nuchal pain) suggested irritation of the roots of the second and third division of the left fifth cranial nerve.

Mastoiditis Without Classic Symptoms.—Dixon states that he encountered 6 cases of atypical mastoiditis in a period of three months. Five of the patients recovered; 1 died. There was no history of an acute infection of the upper part of the respiratory tract. With the exception of 1 patient, whose discomfort began six months before operation, the patients had been ill between four and five weeks. In only 2 instances was there transient slight tenderness to deep pressure. Examination of the external auditory canal showed a narrowing of the canal anteroposteriorly in 3 instances and an elevation of the floor in 2, and in 1 the lumen of the canal was normal. The tympanic membrane was dull, red, thickened and slightly bulging on the patients' first visit. The tympanic membranes of 2 patients with more pronounced bulging were opened, but only blood was discharged for twenty-four hours. One symptom, deep bone ache, was common to all the patients. The pain was constant, and codeine and morphine were required to relieve it. This pain and the distortion of the canal and the drum were the only pathologic indications. The patient who did not recover was first seen ten days prior to his death. His discomfort, deep-seated pain in

and about the ear, had begun two weeks previously. The floor of the canal seemed elevated. The drum was thickened and red but not bulging. During the ten days he performed his usual duties as a butcher, the canal became less swollen, the tympanic membrane lost its redness and the mastoid pain disappeared. The hearing improved. When last seen by the author the patient stated that he did not feel it necessary to return for observation. That night he suddenly became irrational, vomited and showed signs of cerebellar irritation. He was brought to the hospital unconscious. The mastoid cavity was opened. Under a dense cortex, a large perisinal abscess had ruptured into the posterior fossa. Despite blood transfusions and chemotherapy, the patient died within forty-eight hours. This man was the first patient of the series and, the author believes, should have been operated on when first seen. The other 5 patients were operated on with only the deep-seated persistent pain and a dull, thickened drum to indicate operation. The agent of the infection was not established, although routine bacteriologic studies were made. Cultures on brain broth and blood agar of the exudate from the mastoid of 1 patient yielded *Staphylococcus aureus* and *Staphylococcus albus*. The presence of the latter and the fact that all the other direct smears were sterile suggest contamination. The spinal fluid from the patient who died contained the type III pneumococcus.

Rocky Mountain Spotted Fever Virus of Low Virulence.—Topping reports the isolation in the West of a strain of Rocky Mountain spotted fever virus of low virulence. The patient was seen in a hospital in Denver on May 23, 1940. He had been in Wyoming and had arrived in Denver on May 20. On this day a tick was found embedded in an old appendectomy scar and removed by a local physician. On the evening of May 21 the patient had severe chills, headache, muscular pains and, he believed, fever. The next morning he was admitted to the hospital. On May 23 he had a temperature of 103.4 F. and a maculopapular rash. Blood was drawn, and after it had clotted it was macerated in sterile saline solution, and the equivalent of about 4 cc. of whole blood was injected intraperitoneally into 2 guinea pigs. After a prolonged incubation period fever developed in 1 of these guinea pigs, from which the L strain of Rocky Mountain spotted fever was isolated. The strain has been passed through twenty-five generations of guinea pigs. Of 191 animals used 56 were killed either for transfer or for pathologic examination. There were 6 deaths among the remaining 135 guinea pigs, a fatality rate of 4.4 per cent. The rate is considerably lower than that for the mildest strain so far isolated in the East, which has a fatality rate of 8 per cent. Cross immunity tests have been done, and the L strain has given complete cross immunity with the B. R. strain of spotted fever and with the W strain. Other than the lengthened incubation period, the lack of scrotal involvement and a negligible fatality rate the L strain is indistinguishable from the usual strains isolated in the East. The author suggests that the geographic classification be dropped and that in the future strains of Rocky Mountain spotted fever be classified with reference to their high or low virulence for guinea pigs.

Venesection for Erythremia.—Holbrook withdrew from 125 to 750 cc. of blood from 10 patients with erythremia. He found that the venesection promptly relieved headache, nervousness, palpitation and sensations of heat and reduced, at least temporarily, the erythrocyte count, hemoglobin content and viscosity. The duration of the remissions varied; the extremes were a few days and a year. Generally venesection afforded subjective benefit for about two months. The withdrawal of lesser quantities (350 to 450 cc.) of blood seemed more effective than the withdrawal of larger ones (700 to 750 cc.). Failure to effect any symptomatic change for good or bad through venesection occurred after five (in as many patients) of the thirty-seven venesections performed. Blood viscosity tests furnish a reliable means for following the progress of patients under treatment. The results should be checked against erythrocyte counts from time to time. No reticulocyte responses were encountered in fifteen tests made after the withdrawal of 350 to 750 cc. of blood.

Antistreptolysin O in Acute Rheumatism.—Green determined the antistreptolysin O titers of the serum from 1,346 adolescent boys: The mean titer in normal controls was 79; in 82.3 per cent it was less than 125 units. In scarlatina the mean titer was raised to 300, with maximal titers occurring in the third and fourth weeks of infection. In simple pharyngitis due to *Streptococcus hemolyticus* the mean was 263. The mean titer in the active phase of acute rheumatism was 444 and during the inactive phase it was 210. Of one hundred and ten attacks of acute rheumatism, 79.9 per cent were accompanied by a significant increase in the titer, which usually reached maximal proportions at or just after the height of clinical activity, in 10.1 per cent there was no change in the titer and in 3.6 per cent the titer was reduced during the active phase. Either the few patients with acute rheumatism in whom there was no increase in the titer were similar to nonrheumatic patients who failed to react to infection by antibody production or else the infection had no part in inducing the rheumatic state.

Giant Cell Chronic Arteritis.—Gilmour cites 4 cases of a rare and little known form of arteritis which affects the aorta, the branches of the aortic arch and their branches and possibly other arteries. Syphilis was excluded in 3 of his cases and in most of those reported in the literature. Tuberculosis also may be excluded. The essential microscopic change was inflammation, and the prodromal symptoms were strongly suggestive of infection. The microscopic and clinical features do not resemble those in other types of arteritis. It is probable that the disease is a separate entity. In the branches of the arch of the aorta and in the internal and external carotid arteries the distribution of the disease is focal, bilateral and symmetrical, while in the aorta it is usually widespread. The inflammation apparently heals in time, but death has occurred from rupture of an aneurysm or from thrombosis during active inflammation. Multinuclear giant cells were present in most of the affected vessels, therefore the name giant cell chronic arteritis.

Lancet, London

*Blast Injury of Lungs. J. N. O'Reilly and S. R. Gloyne.—p. 423.

Action of Bismuth Carbonate in Gastric Disease.—Alstead tried to determine the value of bismuth carbonate in relieving the pain of gastroduodenal disease and the fate of the salt in the stomach. His in vitro and in vivo experiments do not suggest that therapeutic doses of bismuth carbonate protect the gastric mucosa. After administration the salt collects in the most dependent part of the stomach and tends to adhere to a small area of the mucous membrane in the prepyloric region. The ulcer-bearing area of the stomach is rarely affected. Bismuth carbonate may exert an astringent action on the empty stomach, but even under favorable conditions this action is slight. In practice it must be considered negligible because of the minute amount of bismuth in solution with the mucoprotein of gastric juice. When a gastric astringent is required tannic acid, in the form of glycerin of tannic acid, is more reliable. The antacid effect of therapeutic doses of bismuth carbonate is trivial or entirely absent. Although large doses produce appreciable changes in gastric acidity, the changes are transient, and the side effects of such quantities, especially constipation, cannot be disregarded. In gastroduodenal disease bismuth carbonate is no more valuable than powdered milk or lactose in relieving pain.

Blast Injury of Lungs.—O'Reilly and Gloyne present 17 cases of pulmonary injury from the blast of high explosives. None of the 17 men injured were buried under debris. Shock was profound in 5 and was definite though not dangerous in the others. Dyspnea was a constant feature. Dyspnea continued till death in the 4 patients who died. Cyanosis was a common feature. Two types of pain were complained of—a central deep constant and especially severe pain and a less severe more lateral pain made worse by deep breathing. The less severely injured patients stated that the lateral pain was preventing them from breathing. The central pain disappeared after a few days in the patients who recovered, while the other pain remained for at least a week. Pain in the abdomen was common. At necropsy in each of the 4 cases extrapleural hemorrhages were observed. The intercostal spaces appeared black in contrast to the white bands of the ribs. The hemorrhages may have irritated the intercostal nerves, causing rigidity of the abdominal wall, or damage to the abdominal muscles may have caused the rigidity. A laparotomy should not be performed unless specifically indicated. Free hemoptysis was observed in 2 patients and in the others blood-stained sputum and brightly stained froth in the air passages. A number had a cough after the first twenty-four hours, in some of them troublesome. In patients with uncomplicated injury the cough and sputum disappeared in ten days, but it persisted in those with severe late effects or complications. Restlessness was a constant symptom and bore a direct relation to the severity of the damage. The pathologic observations suggest that the restlessness is due to an irritative cranial lesion. Ruptured eardrums were noted. Purulent otorrhea developed in some patients, and in a few it was extremely resistant to treatment. Roentgenograms of the chest of 7 patients were taken within seventy-two hours of injury. In those with severe injury there was a heavy mottling over large areas of the pulmonary fields. The most striking pathologic feature was an effusion of blood. The chief microscopic characteristics were an extensive outpouring of erythrocytes, the rupture of elastic tissue and capillaries, secondary infection with streptococci and bronchopneumonia. All patients with shock were treated with heat and morphine. Seven patients were given oxygen continuously, and transfusions of blood and/or plasma were given to 5. Unless concomitant hemorrhage exists plasma is indicated. Sulfapyridine was given prophylactically to 5 patients, and when pneumonia developed the dose was increased. The drug was withdrawn when the temperature dropped to normal. In blast injury of the lung rest, which was possible only with morphine, is of prime importance and anesthetics are contraindicated.

Dihydrotachysterol for Infantile Tetany.—Woo and her co-workers gave dihydrotachysterol to 5 Chinese infants (from 4 to 52 days old) suffering from infantile tetany. The pathogenesis of the tetany of these infants probably was a congenital lack of vitamin D and calcium. The diets of 4 of the mothers were deficient in vitamin D or calcium or both. The roentgenograms of 3 infants presented evidence of coexisting rickets. Dihydrotachysterol was highly effective in controlling the tetany in 4 infants. Its effect on the concentration of serum calcium and phosphorus was prompt. After therapy the coexisting rickets of 2 infants showed roentgenologic improvement. Fairly large doses, 1 to 1.5 cc. daily, of dihydrotachysterol for one to four days were necessary to raise the serum calcium to a normal level. Therapy with the drug must be individualized. It is imperative that the blood calcium level be determined at intervals before and after treatment is instituted. The chief advantage of dihydrotachysterol to vitamin D and calcium in the treatment of infantile tetany appears to be its prompt action; the principal objections are its high cost and the danger of hypercalcemia if excessive doses are used.

- Indications for Transfusion of Universal Preserved Blood. R. Fischer.—p. 1024.

Antihormones.—Joël discusses some properties and the clinical importance of the antigonadotropic and of the antithyrotropic substances. The antigonadotropic substance cannot be completely purified but remains associated with the serum globulins. It does not develop in a special organ, but rather in the serum and probably in the reticuloendothelial system. Analysis of pregnancy serums revealed that antihormones are not formed during pregnancy. From this it was concluded that normally the body does not employ antihormones as regulatory devices and that it reacts with antihormone formation only if heterogenic hormones are administered. The antithyrotropic substances are found in the spleen and in the liver of animals treated with thyrotropic substances. Antithyrotropic hormone occurs in normal serum, whereas the antigonadotropic factor is not present in the serum of untreated animals. Antithyrotropic substance occurs in various disorders. In patients with exophthalmic goiter, for instance, it is present in smaller quantities than in healthy persons, whereas in cretins it occurs in larger quantities. The author raises the question whether antihormone formation plays a part in prolonged hormone therapy. Insulin, epinephrine, solution of parathyroid, vasopressin, oxytocin, estrone, thyroglobulin and thyroxine do not cause habituation, but it is generally admitted that habituation is produced by the anterior pituitary hormones that contain protein, that is, gonadotropic, thyrotropic, contrainsular and other hypophysial hormones.

mones. However, the clinician needs to fear the antihormone formation with these latter hormones only, if he injects them daily for periods of months. Gonadotropic substance of human origin (substance prepared from pregnancy urine) does not lead to antihormone formation; however, extracts of mare urine do so, if they are given daily for three months or more. The author thinks that antihormone formation can be avoided by alternating the preparations.

- *Iodine Distribution in Normal and Sclerotic Vascular Walls. P. Masson.—p. 1042.

Anhydrohydroxyprogesterone After Hysterectomy and Castration.—The investigations of Wenner and Joël were made on 2 women of 38 and 40 respectively who had undergone total hysterectomy twenty-eight and thirty days before the administration of the hormone. The ovarian function had been excluded by massive doses of roentgen rays that are used in single carcinoma irradiations. However, the time interval between roentgen castration and hormone administration was relatively short, seven and eight days, respectively. It is of clinical interest that 1 Gm. of anhydrohydroxyprogesterone, given on three successive days, was well tolerated. Chemical analysis of the urine corroborated Frank's observation that no pregnandiol is eliminated after the administration of anhydrohydroxyprogesterone. Two other factors that were detected seem of special interest: 1. The control urine as well as the urine collected after the treatment contained from 0.1 to 0.2 mg. of pregnandiol per liter. This corresponds to the observation made by Jones and Te Linde that hysterectomized women eliminate pregnandiol without the administration of progesterone. From this it must be concluded that it is formed in the body without cooperation of the uterus and even eight days after exclusion of the ovaries. 2. The control urine and the urine collected after treatment contained also approximately 0.2 mg. of androsterone per liter. Thus the formation of androsterone and pregnandiol in the female organism is not dependent on the uterus and probably not on the ovaries. The authors think that in the search for the site of formation the adrenal cortex should be considered, because it plays an important part in the stearin metabolism.

Iodine Distribution in Vascular Wall.—Masson used rabbits for his experiments, because arteriosclerosis can readily be produced in them. Of 6 rabbits which were free from arteriosclerosis 5 were given potassium iodide and 1 was not. In 3 the aorta was free from iodine; in the 3 others only small quantities of iodine were detectable. In the aortas of the animals which had been made arteriosclerotic with cholesterol and had been treated with potassium iodide, it was always possible to demonstrate iodine, and except for the iodine content in 1 animal, the iodine content was always greater than in the nonsclerotic animals. The author concludes from these observations that iodine proves so valuable in arteriosclerosis because the vascular wall as such has a certain affinity for it but that the iodine affinity of the arteriosclerotic wall is especially great. With regard to iodine affinity, the sclerotic vascular tissue behaves like the syphilitic and the tuberculous tissue.

- *Therapy of Tropical Ulcer with 1 per Cent Potassium Arsenite Solution (Fowler's Solution). C. de Castro.—p. 625.

Potassium Arsenite Solution for Tropical Ulcer.—De Castro reports good results in 150 cases of tropical ulcer from the following therapy: The ulcer is thoroughly cleaned with pieces of cotton or of gauze. Scrapings of the tissues at the bottom of the clean ulcer are taken for smears. A swab of absorbent cotton is soaked in a 1 per cent potassium arsenite solution (Fowler's solution) and introduced into the ulcer in

such a manner as to have it in constant contact with all the excavations, bottom and borders of the ulcer for ten minutes. Then it is removed and replaced by a piece of plain gauze and the treatment repeated every day up to the disappearance of spirilla in the smears, which, as a rule, takes place in four days and coincides with diminution of the secretion and cleaning of the ulcer. At this point the application of potassium arsenite is stopped and replaced by application of an ointment which is prepared with petrolatum, yellow mercuric oxide, zinc oxide and hydrous wool fat. Complete healing is obtained in about one month. The scars are fine, flexible and smooth. The treatment is moderately painful, but it is well tolerated. For children and for persons sensitive to pain it is advisable to induce a light superficial imbibition anesthesia with 2 per cent procaine hydrochloride immediately after cleaning the ulcer and before applying the potassium arsenite solution. The therapy can be given to ambulant patients. It is practical, economical, harmless and reliable. Early in its course the necrotic tissues of the ulcer are eliminated, the secretion is favorably modified, the bad odor of the ulcer is controlled and the ulcer is sterilized.

Sulfanilamide Therapy in Gastrointestinal Diseases. W. Nimeh.—p. 57.
*Sulfanilamide in Therapy of Chancroid. L. G. Vazquez Vega.—p. 70.

Sulfanilamide for Chancroid.—Vazquez Vega reports good results from sulfanilamide therapy for chancroid, alone or complicated by acute suppurative adenitis, for chancroid phymosis and for phagedenic chancroid. The drug may be given either locally, in the form of powder, or by mouth. When the local treatment is used the entire chancroid or adenitic lesion is covered with sulfanilamide powder (which is obtained by pulverizing sulfanilamide tablets) and dressed with plain gauze; the treatment is changed every day or every other day until healing of the chancroidal lesion. In cases of chancroidal phymosis a 25 per cent suspension of the drug in petrolatum is prepared, and a swab of cotton is soaked in the preparation and brought into contact with the lesion. The duration of the local treatment depends on the clinical reaction. Generally the patient is cured in two weeks. The treatment is harmless and efficacious and may be given to ambulant patients.

*Functional Test of Stomach. R. Chamorro-R. Salinas.—p. 139.

Test for Gastric Cancer.—Chamorro-R. Salinas explores and evacuates the fasting stomach by means of Einhorn's tube. He then introduces 250 cc. of a 5 per cent alcoholic solution to which several drops of a 1 per cent solution of methylene blue have been added. After that he aspirates every fifteen minutes specimens of fluid showing a homogeneous blue. The intensity of the coloration gradually subsides until it has completely disappeared. Normally the coloration persists for twenty-four hours and more and is independent of the gastric acidity. However, the author states that in the presence of gastric cancer, and gastric cancer only, an ascending discoloration can be observed in the test tubes; at the end of an hour they are completely colorless, or at the most they show a blue ring at the upper rim. This metachromatic discoloration has no connection with anaecidity, the presence of organic acids or blood, and the author regards it as specific for gastric cancer.

Electrocardiographic Investigations During Electric Shock.—Streit describes electrocardiographic studies on 39 schizophrenic patients who underwent electric shock therapy. In all, one hundred and ninety electrocardiograms were made after thirty-five total shocks and thirty abortive shocks. The changes after total shock are mostly disturbances in the rhythm. At first there is usually a sinus tachycardia up to 250 beats per minute. After this has subsided, various types of arrhythmia appear (sinus arrhythmia, auricular and ventricular extrasystoles, combinations of auricular and ventricular extrasystoles with vagus arrhythmia). The T wave is elevated immediately after the attack, but three to eight minutes later it passes through a phase of flattening. At the end of one to two hours the changes disappear. The ST interval is lowered in approximately 25 per cent of the cases. This lowering of the interval often accompanies an elevation of the T peak. Of two electrocardiographic recordings made during the latent period one shows, in addition to a sinus tachycardia, an elevation of the T wave and the second a slight flattening of the T wave. During the abortive shock, rhythmic disturbances are rare; auricular and ventricular extrasystoles were observed in 3 cases. The abortive shock is characterized by severe bradycardia and cardiac arrests. The irregularities in the heart beat are the most important of the electrocardiographic changes during electric shock. Immediately after the attack, the irritation of the sympathetic, with sinus tachycardia, predominate; some minutes later, vagus effects become evident, in that now there are also a sinus and vagus arrhythmia and auricular, and somewhat less often ventricular, extrasystoles. Generally, the extrasystoles disappear after four or five minutes. The many extrasystoles after electric shock were a surprise, since Bini and Cerletti, the investigators who developed the electric shock therapy, observed only mild arrhythmias with extrasystoles and considered them insignificant. Streit's observations indicate that the electrocardiographic aspects of electric shock are similar to those of metrazol shock. The electric shock therapy is not without danger for the circulation. The cardiac arrests may, under certain conditions, lead to permanent heart failure and the frequent rhythmic disturbances to ventricular fibrillation.

Treatment of Pellagra with Nicotinic Acid Amide.—Schroeder and Dramoff state that pellagra in Bulgaria occurs endemically in regions in which maize and wheat grits are the only sources of protein in the diet. These vegetable proteins require the pellagra preventive substance for their proper utilization; that is, the intake of large quantities of maize or wheat grits increases the requirements for the antipellagra factor. The toxic action of vegetable proteins is often accompanied by porphyria. This disorder is a constant symptom of pellagra, and it is encountered also in favism (bean poisoning) or in lathyrism. Porphyria causes light-sensitivity of the skin of pellagrins. The treatment of pellagra has been greatly simplified since the discovery of the pellagra preventive substance. However, it should be remembered that pellagra is rarely a monovitaminosis. The pellagrous manifestations of the gastrointestinal tract, of the skin and of the nervous system yield rapidly to treatment with nicotinic acid, but the general weak-

ness and anemia require the simultaneous administration of the other factors of the B complex in the form of yeast or liver extract. In order to insure a permanent cure of pellagra it is necessary to change the diet or to administer the entire B complex. The daily dose of nicotinic acid or of nicotinic acid amide is between 100 and 1,000 mg. It has proved advantageous to give 60 to 125 mg. four times daily by mouth. Beef, pork, rabbit meat, hog liver, milk, Savoy cabbage and yeast are rich natural sources of the pellagra preventive substance.

Anuria After Transfusion of Conserved Blood.—Brunner says that at his clinic the transfusion of conserved blood produced practically the same results but also the same complications as did the transfusion of fresh blood. Rarely he saw more severe reactions after the transfusion of conserved than after the use of fresh blood. He thinks that a final evaluation is still impossible, since numerous investigations are still uncompleted. He does not share the view expressed by Jeanneney and his collaborators, according to which the danger of transfusion shock is less after the transfusion of conserved blood than after the transfusion of fresh blood, because the colloidal state of conserved blood is already stabilized and its composition can be better controlled. The author warns against too great optimism in this respect and reports 3 cases in which anuria resulted following the transfusion of conserved blood. Blood transfusion was indicated on account of shock. All recipients had blood of group O, and so did the donors, with one exception, when homogenized blood was used from four donors with group O blood and one donor with group A blood. The transfusion, which in each case provided 300 cc. of blood, was given, with additional physiologic solution of sodium chloride, in the form of an intravenous drip lasting for two or three hours. The preliminary biologic tests never disclosed disturbances, and there were no reactions during the transfusion. The ages of the conserved bloods varied from eleven to thirty-two days, but in the first patient, even the eleven day old blood produced a thirty-six hour anuria with subicterus as the result of massive hemolysis. It is possible that an accidental unilateral ureteral ligature contributed to the anuria, which, however, was first elicited by the hemolysis. Subsequently there developed a refractory renal insufficiency with dynamic ileus without peritonitis. In the second case, of the most severe anuria, the course terminated in death five days after the transfusion of conserved blood, because the anuria failed to respond to alkali therapy, to diuretics, to vasodilator agents or to lumbar anesthesia. Renal decapsulation or denervation was impossible on account of the greatly impaired general condition. In the third case, in which the homogenized conserved blood was used, the course was the same as in the 2 others. Following anuria of thirty-six hours' duration, renal insufficiency developed which seventeen days later terminated in death from uremia.

Anaphylactic Reaction After Electroresection of Prostate.—Arnholdt reports on a man aged 76 with hypertrophy of the prostate complicated by considerable renal damage and mild urinary infection. Electroresection was carried out with the aid of local anesthesia, after two weeks of preliminary treatment. The prostate had no median lobe, but the two lateral ones, particularly the right one, considerably constricted the

urethral lumen. About 3 Gm. of tissue in all was resected from the two lobes. Moderate hemorrhage was readily arrested, and a catheter was introduced. The postoperative course was uneventful, but the result was unsatisfactory in that the residual urine still amounted to 170 cc. After thirty-three days, the electroresection was repeated, the removed prostatic tissue again amounting to 3 Gm. Three to four hours after the second electroresection there appeared, along with a sensation of extreme heat and itching, erythema and swelling of skin, particularly on the face and the extremities. The patient was given, immediately and on the following days, intravenous injections of 10 cc. of calcium-Sandoz. The cutaneous manifestations and the temperature increased on the following day and reached their maximum in the afternoon. The swelling and the exanthem involved the entire body but were especially severe on the face. Respiration was accelerated, and the pulse was soft and frequent. There were severe head and muscular aches and itching and burning of the eyes. With desquamation of the skin, the symptoms gradually subsided in the course of three days. The exanthem resembled a severe urticaria. The clinical picture indicated a toxic or allergic genesis. The patient had received only the medicaments he had been given before and had eaten nothing but the customary breakfast. The author concludes that the anaphylactic reaction was caused by the combustion products of the electroresection, pointing out that the electric current denatures the homogeneous cell protein into a heterogeneous substance, which sensitized the body during the first electroresection; that is, in the course of days the patient became allergic and the renewed electroresection elicited the anaphylactic reaction.

Amyloidosis in Chronic, Not Suppurative Affections of Joints. R. Gordin.—p. 2609.

Gonadotropic Substance in Urine in Tumor of Testis.—Furuhielm studied 44 cases of malignant tumor of the testis and 1 of extragenital tumor that produced gonadotropic substance. There were 21 cases of other lesions of the testis and 69 other cases of different diseases in men as controls. He found the secretion of gonadotropic substance in the urine an aid in diagnosis in cases of tumor of the testis. However, increased secretion of gonadotropic substance also occurs in certain other diseases in men, and the biologic percentage of error must be considered. He states that in hormone analysis qualitative hormone differentiation according to Hamburger is of great value. If chorionic gonadotropin is secreted, mixed epithelioma is most likely. If in addition the pregnancy reaction is positive, chorioepithelioma can be suspected. If the follicle stimulating factor is established in increased amounts, a seminoma is indicated. Even if it does not agree with the histologic diagnosis, hormone analysis may be decisive for therapy and prognosis. Tumors of the testis which secrete chorionic gonadotropin usually have only a transient radiosensitivity, while those which secrete the follicle stimulating factor are often more sensitive to roentgen treatment. The prognosis is most favorable in the cases in which less than 165 mouse units of the follicle stimulating factor is secreted. It is especially unfavorable if both kinds of gonadotropic substance are established.

Book Notices

The Treatment of Infantile Paralysis in the Acute Stage. By Elizabeth Kenny. Cloth. Price, \$3.50. Pp. 285, with 72 illustrations. Minneapolis & St. Paul: Bruce Publishing Company, 1941.

This book represents an attempt to present the argument that spasm is the damaging and ever present symptom of the disease infantile paralysis. Miss Kenny describes in infinite detail the treatment of infantile paralysis in the acute stage by means of hot wet compresses without splints or braces. The terminology used is somewhat confusing. Any physician who has been thoroughly grounded in physiology, anatomy and pathology and has observed the degenerative changes in the anterior horn cells of the spinal cord of a monkey or of a human victim of acute anterior poliomyelitis will find much in the Kenny theory that is absurd and unscientific. The confusing discussion of pathologic principles and the rather odd mixture of anatomic terms and descriptions make it difficult to read the book or to follow some of the arguments by the author.

Spasm is often present in the early stages of acute anterior poliomyelitis and as such has been seen by every one who has studied the disease. Miss Kenny has definitely shown that the early application of hot wet dressings properly applied will aid in the reduction of the amount of muscle spasm, in the relief of pain and in the recovery of the patient. On the other hand, she has failed to recognize that fibrous tissue replacements of muscles, subsequently producing shortening and actual contracture, are not spasm. The enthusiasm of this remarkable woman is shown in every chapter of the book. This enthusiasm borders on religious fanaticism. Also she is completely on the defensive. In this book she has described her early experiences in Australia and England and the more recent and perhaps more pleasant years in Minneapolis.

The Kenny opposition to the use of splints is undoubtedly engendered by the fact that she has seen a great many patients with joints stiff and muscles fibrosed by unwise, prolonged, total immobilization. To this extent her argument is well taken. However, there are patients for whom certain types of splints are important even during the acute or subacute stages of the disease. There are patients who would undoubtedly die of respiratory paralysis if they were not placed in a respirator. There are other patients who would never walk a step without the aid of the braces which she condemns.

The medical profession of the world owes to Sister Kenny a debt of gratitude for having made us realize that prolonged splinting without exercise, without heat and moisture applied to the limbs, is harmful. It is hoped, however, that the public and the medical profession in general will not be so completely swayed by the enthusiasm of this remarkable woman that they will refuse to use splints where only splints can prevent deformities or will refuse braces when only through braces can independent and self care be made possible. We should be sufficiently liberal minded to accept the good elements of the Kenny theory without losing our balance and falling head over heels into a pit which both Galen and Hippocrates succeeded in climbing out of many centuries ago.

Surgery of the Heart. By E. S. J. King, M.D., M.S., D.Sc. Cloth. Price, \$13.50. Pp. 728, with 268 illustrations. Baltimore: William Wood & Company, 1941.

The author is honorary surgeon to outpatients, Royal Melbourne Hospital of Melbourne, Australia. The book originated as a dissertation prepared by the author and submitted to the Royal College of Surgeons in 1938. It was awarded the Jacksonian Prize. The book is divided into two sections. The chapters in the first section are on the development of the heart, comparative anatomy of the heart, the anatomy of the heart, developmental abnormalities of the heart, histology of the heart, physiology of the heart, pathology of the heart, radiology in examination of the heart and electrocardiography. The chapters in the second section are on the surgical approach to heart diseases, experimental investigations, diseases of the heart, diseases of the myocardium, diseases of the coronary vessels, diseases of the endocardium, diseases of the pericardium, diseases

of the great vessels, diseases of the pulmonary artery, diseases of the pulmonary veins, diseases of the aorta and diseases of the venae cavae.

The book is more than a surgical treatise. A large part is devoted to nonsurgical subjects. The author is thorough in his review of the literature. This is the most valuable feature of the book. Any one desiring a bibliography will find it readily available.

The literature on the surgery of the heart presents difficulties in the way of analysis. The total number of operations on the heart is not large when compared to operations on other organs, and the experiences of any one surgeon are relatively few. This lack of broad experience results in a paucity of data on the subject. The surgical experiences are inadequate to give a final answer to many questions. We deal then with the expression of opinions and some of these are of a conflicting nature. The author does almost as well as can be expected with material of this nature. For example, he advocates opening the pericardium in patients with enlarged heart. After advocating this operation he concludes that "the indications for the procedure are not yet known; a great deal of information is required before they can be determined exactly. On the other hand, the operation may be performed readily under local anesthesia and without appreciable risk. For this reason the specification of rigid criteria is not, in the early stages of investigation, so important as it is for technically formidable procedures." After reading the discussion of this subject, the reader cannot be certain whether this operation should be applied. If it is as good as the author claims it to be, why has the operation not been done more frequently so that the indications are clearly known? It is obvious that additional critical experiences are necessary to ripen this subject. Similar statements can be made about other subjects discussed in the book. The reviewer doubts whether heart surgery is far enough developed for a book.

Cancer of the Face and Mouth: Diagnosis, Treatment, Surgical Repair. By Vilray P. Blair, M.D., Sherwood Moore, M.D., and Louis T. Byars, M.D. Cloth. Price, \$10. Pp. 599, with 324 illustrations. St. Louis: C. V. Mosby Company, 1941.

This is a new and important study of an old and extremely important subject. Washington University and its associated hospitals in St. Louis have afforded the "terrain" on which these three authors, working as a team, carried out intensive studies on epithelial cancer in 1,500 cases over a period of twenty years. A foreword by Dr. J. M. T. Finney sets forth the "right" of these men to authoritative consideration.

One would assume that external malignant growths afford the best chance for early diagnosis. Not so here. Only from 5 to 10 per cent of all cases can be classified as "early." Three reasons are cited: 1. The patient refuses the diagnosis or accepts it and demands a guaranteed cure. Most often he becomes the victim of quackery and returns too late to his first adviser. 2. There is a lack of diagnostic acumen when diagnosis might have been made early. 3. Misinterpretation occurs of the microscopic report of the pathologist who writes "no cancer found," which is not at all understood by the practitioner when he assumes that this means no cancer present. Moreover, one is likely to regard cancer of the mouth or face as "mild," but some of these growths are terribly malignant from the outset, notably cancer of the sinuses, "usually of the highest grade of malignancy." The diagnostician must depend on his eye, his finger, the knife and the microscope. When all of these are given their true weight, the patient's chances of life extension are multiplied many times.

One concludes from this book that the authors believe surgery the method of choice in this field. Irradiation holds second place save in those advanced cases in which surgery seems impossible. But at operation the surgeon must avoid "grafting" spilled cancer cells into a fresh wound, and he must not "squeeze" these cells into the general blood and lymph circulation.

These principles are so axiomatic that they are probably overlooked now and then. In any event the salvation of the patient depends on early diagnosis, prompt, effective treatment, selection of the correct treatment for the individual case and persistent execution of "the plan" originally set down.

Chapter XVIII, written by Dr. Sherwood Moore, deals with irradiation; that is, with the use of roentgen rays, radium or

radon, singly or in combination or in sequence. While these agents may be extremely useful, especially in making cancer more "tolerable," they can cause a fatality. It is difficult to control them completely; they act on normal cells adversely as well as on diseased cells. In the general body economy they may cause acidosis or, at least, increase it and may bring about "roentgen sickness," the symptoms of which are anorexia, general malaise, nausea, sometimes vomiting and, if treatment extends over the abdomen, intractable diarrhea. Under such conditions the situation gets entirely out of hand, and the patient hurries to his doom.

While there are no colored plates in the book, the multiplicity of excellent photographs and the prodigality with which line drawings have been showered on the pages in order that the reader may thoroughly understand operative technic, plus the quality of paper and print, make this volume first in its field, and one may predict its usefulness over a long span of years to come.

Diseases of the Blood and Atlas of Hematology with Clinical and Hematologic Descriptions of the Blood Diseases Including a Section on Technic and Terminology. By Roy R. Kracke, M.D., Professor of Bacteriology, Pathology and Laboratory Diagnosis, Emory University School of Medicine, Atlanta. Second edition. Cloth. Price, \$15. Pp. 692, with 100 illustrations. Philadelphia, Montreal & London: J. B. Lippincott Company, 1941.

The second edition of this excellent book has been enlarged by the addition of one hundred and sixty pages, ten new color plates and twenty-nine other new illustrations. Among the new material are data on the fractionation of liver extract, new chapters on hemolytic anemias and hemoglobinuria, new material on the action of drugs on the blood, hemoglobin and its derivatives, transfusion and the operation of a blood bank, the use of blood plasma and recent work on the bone marrow. There is a section on vitamin K and new material on the treatment of leukemia. The plates and pictures are unusually good, and the text is presented in a clear cut fashion with the free use of outlines and specific definitions. The section on the blood in animals will be welcomed by many experimenters. The chapter on hematologic technic is extensive and detailed. The bibliography has been brought up to date and the index is extensive. The book is now well established as one of the classics of hematology and is indispensable for any one looking for authoritative, comprehensive and well ordered data on blood.

The Microbe's Challenge. By Frederick Ebersson, Ph.D., M.D., Director of Laboratories; Pathologist, Gaillinger Hospital, Washington, D. C. Cloth. Price, \$3.50. Pp. 354, with portrait. Lancaster, Pa.: Jaques Cattell Press, 1941.

For the reader who wants detailed and technical information about bacteria translated into terms understandable for the layman, this is an excellent, if difficult, book. The book is as clear an explanation of highly technical relationships as could be expected, in view of the difficulties of translating specialized scientific materials into language readily understood by the nonprofessional reader. The book contains chapters on the fundamental facts relating to bacteria in general, the historical background of our knowledge of bacteriology, the ways of parasites, changes and variations in microbe life, the chemical behavior characteristics of bacteria, vaccines and viruses and insect borne diseases. Research and a survey of the situation today are each made the subject of a chapter. The book is exceptionally well made and beautifully printed with a clear type face generously leaded. Its only illustrations are a frontispiece photograph of Louis Pasteur, an insert page showing the first microscope on one side and van Leeuwenhoek on the other, an occasional drawing after the manner of woodcuts and a map showing distribution of plague in Manchuria in 1910. There is an adequate glossary and a satisfactory index.

The Complete Weight Reducer. By C. J. Gerling. Cloth. Price, \$3. Pp. 246. New York: Harvest House, 1941.

The title—and some of the subtitles on the slip cover: "The Modern Spot Reducer," "Manual of Slimming Garments"—filled the reviewer with apprehension, which however was largely relieved after reading the text. The book is written for the "average reducer," i. e. for the interested layman, and may be used as a dictionary, the various points of interest being listed in alphabetical order. It has practical merit mainly in describ-

ing and exposing most of the popular quackeries and frauds and in stressing the dangers of self prescription as well as the necessity of medical consultation. In its more ambitious aims—when it tries to explain metabolic processes, the role of endocrine glands, the importance of heredity—it is less successful, as such points do not lend themselves to categorical, lexicographic presentation. Altogether, the book should be popular with those "reducers" who want some information on their problems even though it is not always truly instructive and in some instances (effect of exercise on local fat deposits) inaccurate.

Die Grösse und Form der roten Blutkörperchen bei Menschen verschiedenen Alters unter physiologischen Verhältnissen. Von Carl August Hernberg. Acta medica Scandinavica, Supplementum CXXII. Paper. Pp. 92, with 21 illustrations. Helsingfors: Mercators Tryckeri, 1911.

This monograph presents a comprehensive review of the literature and an analysis of the blood of 236 persons studied by the author. The data are divided in seven age groups: infants under 14 days, children from 2 months to 4 years, school children from 6 to 12 years, boys and girls from 13 to 19 years, adults from 22 to 39 years, a middle aged group from 42 to 60 years and persons from 62 to 90 years. The data for each patient are given and analyzed in terms of age and sex. In these groups the average red blood cell volume, anisocytosis and poikilocytosis ran parallel to the average diameter. In boys at puberty the average diameter was slightly larger than that of the erythrocytes of the girls. Cell thickness was slightly increased during the 6 to 12 year period. After puberty (most marked in the 20 to 40 year group) the red blood cell count and hemoglobin percentage were higher in men than in women, although in old age the difference was not considered significant mathematically. The red blood cell diameter was largest during the first two weeks of life, smallest during the period of 2 months to 4 years and in the adult range after puberty. The monograph is illustrated with twenty-one graphs and twenty-six tables, and an extensive bibliography is appended. It is an excellent reference work on normal blood.

Practical Methods in Biochemistry. By Frederick C. Koch, Frank P. Hixon Distinguished Service Professor of Biochemistry, University of Chicago, Chicago. Third edition. Cloth. Price, \$2.25. Pp. 314, with 15 illustrations. Baltimore: William Wood & Company, 1941.

This edition of a laboratory manual for medical students carries forward the high ideals and scholarship of previous editions. New methods on uric, lactic and pyruvic acids are added. Extension to include qualitative and quantitative experiments on vitamins and hormones was considered but omitted because of the costly equipment necessary to insure results commensurate with the time and energy spent. This consideration of the student, in a field in which the author is a distinguished contributor, shows the soundness of his judgment and ideals: What cannot be done well, do not attempt. The author realizes that the student who brings much to a subject gets more out of it. He expects the user of the book to have sound fundamental training in chemistry, physics and biology. With this equipment this manual is well suited to guide him in biochemistry. The methods are given in clear and accurate terms. The illustrations of the more complicated apparatus are excellent and explanatory. The contents of the book are divided into three parts: (1) the chemistry of cell constituents, (2) the chemistry of the digestive tract and (3) blood and urine. The student who uses this manual as the instructions direct has every opportunity to become familiar with modern biochemistry. Those who wish a review in biochemical methods will find it a source of enlightenment.

Diseases of the Veins and Lymphatics of the Lower Extremity: A Manual of Veins and Lymphatics of the Lower Extremity for Students and Practitioners. By C. H. Verovitz, M.D., Demonstrator of Surgery, Western Reserve University School of Medicine, Cleveland. Cloth. Price, \$6. Pp. 392, with illustrations. Boston: Christopher Publishing House, 1941.

This monograph contains much valuable material and many useful diagrams described by an author with obvious clinical experience and a keen power of observation. The poor organization of the subject matter, the loose grammar, the faulty spelling of names and the careless list of references, with titles and journals frequently misquoted, greatly detract from the value of the book. With careful editing and better organization, future editions might provide easier and more profitable reading.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

SULFONAMIDE DRUGS IN SINUSITIS

To the Editor:—I read in *The Journal* that a 5 per cent solution of sodium sulfathiazole is useful in the treatment of sinus trouble. I read later that this solution is alkaline and irritating. May I ask whether sulfanilamide or azosulfamide is effective as a spray when used in the same way and, if so, in what per cent solution? Are solutions of these irritating? Also I should like to ask whether sulfanilamide or sulfathiazole powder would be effective if blown into the nose with a powder blower, and, if so, whether it would be irritant or contraindicated in any way?

R. P. Little, M.D., New York.

ANSWER.—There is little evidence that a 1 per cent solution of sulfanilamide in physiologic solution of sodium chloride or that a 5 per cent solution of azosulfamide is of value as a spray or as an irrigating solution in the treatment of sinusitis. It is not likely that either solution would be irritating to the mucous membranes of the nose and throat. There are no reports concerning the introduction of sulfanilamide or sulfathiazole powder into the nose by means of a powder blower, although these drugs in a finely powdered form have been used as a medicinal snuff in attempts to eliminate hemolytic streptococci and staphylococci from the nasal passages. When these drugs have been used in this manner there have been mild degrees of irritation (such as slight itching and burning of the nasal mucous membranes and a watery discharge) noted. There are no extensive reports regarding the effectiveness of the powdered sulfanilamide or sulfathiazole in the control of sinus infections.

MANNITOL HEXANITRATE AS VASODILATOR

To the Editor:—It has recently come to my attention that mannitol hexanitrate is being advocated for use as a vasodilator in competition with erythrol tetranitrate, glyceryl trinitrate, sodium nitrite and even bismuth subnitrate. Where should one classify the usefulness of mannitol hexanitrate in comparison with other vasodilators and how does it compare with them in rapidity and duration of action?

David Stein, M.D., Philadelphia.

ANSWER.—All the compounds listed in the question depend for their action on the liberation of the nitrite ion within the body. This action consists in a relaxation of smooth muscle tissue and is independent of innervation. Mannitol hexanitrate has never come into general use in the practice of medicine despite the fact that it has been known as a vasodilator for many years and has been recently revived. The reasons for this are that it is inferior to glyceryl trinitrate (nitroglycerin) and amyl nitrite for quick effect and to sodium nitrite for intermediate effect (relatively slow initial but more prolonged action) and apparently is little or no better and no less toxic than erythrol tetranitrate for an effect that lasts for hours. Goodman and Gilman (*The Pharmacological Basis of Therapeutics*, New York, Macmillan Company, 1941, p. 552) have published a table listing the characteristics of the vasodepressor response of hypertensive patients receiving full therapeutic doses of certain preparations which release the nitrite ion in the body. The substance of this table can be summarized as follows:

	Fall Begins, Minutes	Maximal Fall Reached, Minutes	Extent of Fall,* Mm. of Mercury	Time of Recovery, Minutes
Amyl nitrite.....	1/2-1	2-3	15-25	4-8
Glyceryl trinitrate.....	1-2	5-10	15-30	25-40
Sodium nitrite.....	5-20	25-40	25-40	60-150
Erythryl tetranitrate....	15-30	30-50	30-40	180-300
Mannitol hexanitrate.....	15-30	60-120	30-40	240-360

* Systolic blood pressure.

It is true, however, that mannitol hexanitrate has not, at least in recent years, had the clinical trial that the other nitrites have had. Further experience might or might not reveal a value not now known; disappointment in the clinical applicability of erythrol tetranitrate suggests, however, the probability of similar disappointment in the practical use of mannitol hexanitrate.

TREATMENT OF TRACHOMA

To the Editor:—Will you kindly send me information on the treatment of trachoma with sulfanilamide? What other treatment is indicated?

Eleanor T. Calverley, M.D., Hartford, Conn.

ANSWER.—The treatment of trachoma with sulfanilamide and its congeners, originally described by Fred Loc of the Indian Medical Service, was said by Edward Jackson, the dean of American ophthalmologists, to be the greatest advance in the therapy of that disease in two thousand years. Interestingly enough, Loc's original technic of giving 1/2 grain (0.02 Gm.) of the drug by mouth per pound of body weight in twenty-four hours has never been improved on. Three courses of five to seven days each with an intervening rest period of three days suffice in nearly all cases. The blood level of sulfanilamide should be maintained during that time at between 3 and 4 mg., and naturally all precautions as to bodily health should be observed. No local treatment need accompany the internal use of the drug except a nonirritating cleansing solution to keep the conjunctival sac free from secretion.

Practically 75 to 90 per cent of cases of trachoma in stages 1 and 2 may be cured. Although there is an immediate relief of subjective symptoms, objective subconjunctival hyperplasias require from six weeks to six months to disappear and final judgment should not be passed until at least one year has elapsed. But of even greater importance than the cure is the fact proved by Thygeson that the disease cannot be transmitted after four days' use of sulfanilamide.

In stages 3 and 4 in which scar tissue contraction has occurred, brilliant results cannot be expected. Relief from secondary infection and relief from the pain of corneal trachoma are accomplished and the patient is made comfortable. The disease is no longer susceptible of transmission, but the usual local measures are necessary because of the scarring.

IONTOPHORESIS FOR FUNGUS INFECTION OF NAILS

To the Editor:—Has copper iontophoresis ever been used in the treatment of fungus infections of the toenails? What were the results?

M.D., London, Ky.

ANSWER.—Although Lowenfish treated 10 cases of dermatophytosis by "cataphoresis" employing various fungicides, among which was copper, he concluded that the method was of "no value." Subsequent investigations by Haggard, Strauss and Greenberg and by Hoechstetter indicate that copper iontophoresis is valuable in treatment for fungus infections of the hands and feet.

Haggard and his associates found that 26 of 37 patients obtained "clinical cure"; and Hoechstetter, using the same method, reported that 16 of 18 cases of fungus infection of the feet were "clinically healed" following copper iontophoresis.

Gunderson reported that he employed iontophoresis only if other methods failed and said that his experience suggested that there were no contraindications to the use of copper iontophoresis. Gunderson recommended copper iontophoresis as the treatment of choice in stubborn cases and used it in preference to roentgen therapy. However, he resorted to the use of iontophoresis only if other methods failed.

USE OF BLOOD FOR PREGNANCY TEST

To the Editor:—Would you tell me what are the comparative merits of using blood instead of urine for the Friedman test for pregnancy? I have in mind the Hofmann modification of the Friedman test, in which from 10 to 13 cc. of blood serum which has been extracted with ether is injected intravenously in the test rabbit, and autopsy performed in twenty-four to thirty-six hours. Reference to this test may be found in the *Journal of Laboratory and Clinical Medicine* 22: 508 (Feb.) 1937

T. T. Rackliffe, M.D., Los Angeles.

ANSWER.—The test referred to is a recognized procedure which gives excellent results. The advantages over the Friedman test are those of speed and availability of a sufficient amount of hormone in the blood at any time of day. With the serum recovered from about 12 cc. of blood, a result can be read macroscopically in twenty-four hours. The blood may be drawn at any time of the day without respect to meals or other factors, while in the urine test a morning specimen after restricting fluid intake for twelve hours is most satisfactory.

The only objection to the use of serum is that there is a greater chance of obtaining a toxicity from this material. Because of this there may be a higher rate of mortality among the test animals, probably as a result of protein shock from the serum used. The washing of the serum with ether is a step in the reduction of test animal mortality, as the ether acts to detoxify the serum.

Details of the technical procedure involved may be found in *Clinical Laboratory Methods and Diagnosis* by R. B. H. Gradwohl, published by the C. V. Mosby Company.

SYPHILOPHOBIA OR SYPHILIS WITH NEGATIVE SEROLOGIC REACTIONS

To the Editor:—Please inform me whether any cases of syphilis in which the serologic reaction is persistently negative are known and how they may be explained. I have a syphilophobe under treatment whom I am trying to convince that he is free of the disease but who persists in believing that his is a rare case because the reaction of the blood serum is consistently negative, a condition which I had to admit is theoretically possible although I have never seen it. To the best of my knowledge a consistently negative Wassermann, Kahn or Kolmer reaction, or preferably a combination of these, is, in the absence of clinical symptoms of syphilis, positive proof of the absence of syphilitic infection.

R. W. Mueller, M.D., Los Angeles.

ANSWER:—Yes, it is possible for a person with syphilis to have a persistently negative serologic reaction. So-called burnt out tabes is a good example of this. Unfortunately, there is not enough information on this patient to assist much in formulating an answer. Did the patient ever have syphilis? That is the first thing to decide. If the patient has had a consistently negative Wassermann, Kahn or Kolmer test, or a combination of these, with an absence of clinical symptoms of syphilis, then there seems to be no reason why he should be treated.

On the other hand, if the patient has had syphilis, then he must have had sufficient continuous therapy, with alternating courses of an arsenical and of a bismuth compound for a year to eighteen months; his blood serologic reactions must have been negative for at least a year; lumbar puncture must give negative results, and the examination of the cardiovascular system must show no evidence of syphilitic involvement in order to warrant the stopping of therapy.

Unfortunately, the physician does encounter patients with syphilophobia who will take treatment just as long as they can get the physician to give it to them. Such patients are really a problem for the psychiatrist.

PROGNOSIS IN PAROXYSMAL TACHYCARDIA AND QUINIDINE

To the Editor:—1. A man of 22 has had attacks of paroxysmal auricular tachycardia since the age of 12, now occurring about once a week. These attacks he controls by holding his breath and bending over. Physical examination is essentially negative except for his excessive height, 6 feet 4 inches (193 cm.), and low weight, 145 pounds (66 Kg.). There is no past history suggestive of any etiologic factors for heart disease on physical examination or from his system review. Would you please tell me if I am correct in giving him a good prognosis?

M.D., Massachusetts.

2. A woman of 29, otherwise in good health, has had disturbing attacks of paroxysmal auricular tachycardia, confirmed by electrocardiogram, for about four years. At first these were as frequent as ten or fifteen a day, but she has responded well to quinidine, 20 grains (1.3 Gm.) daily. She has two bad wisdom teeth, which may have a bearing on the condition. She has asked me whether she will ever recover completely from the attacks, and I have been unable to find any answer to her question. When this arrhythmia is present without other illnesses (that is, in healthy young adults), what is the likelihood of spontaneous cessation of attacks, and does medication such as quinidine (which controls this patient's attacks) have any permanent effect in stopping the attacks?

E. C. Heyde, M.D., Wooster, Ohio.

ANSWER:—1. From the facts given it would appear that a good prognosis is entirely warranted. There is a fair likelihood that the number and severity of the patient's attacks will decrease as the years pass, but even if this does not occur they will probably not prove incapacitating.

2. A fairly large number of young patients with paroxysmal tachycardia who are otherwise healthy recover spontaneously. Reliable figures are not available, in part because many such patients probably fail to come under the care of physicians. There is no evidence that quinidine has any permanent effect in stopping the attacks. In some patients so treated the attacks do not recur after cessation of therapy, but as indicated the tendency frequently stops spontaneously and the efficacy of the quinidine cannot be proved. In this connection, because quinidine acts by virtue of being a protoplasmic poison, it would seem wise to stop it at intervals in the hope that spontaneous recovery may have occurred. This is especially true if as much as 1.3 Gm. of quinidine a day is necessary to control the attacks.

KNOCK KNEES IN YOUNG CHILD

To the Editor:—Can you please give me information on the treatment of knock knees in a child of three years and eight months? The condition is of rachitic origin. The child has been receiving 10 drops of percomorph liver oil twice daily since July, 1939. At times he urinates too frequently; should the dose be decreased? His height is 41½ inches and his weight is 48 pounds. Is it possible that the deformity will decrease as the leg lengthens?

M.D., Canada.

ANSWER:—If the knock knee is not produced by some generalized disturbance such as rickets or osteodystrophy the treatment would depend to some extent on the severity of the deformity. If the deformity is mild a slight change in the weight-bearing thrust obtained by applying Thomas heels wedged ¾ inch (0.48 cm.) on the inner side of the shoes will frequently bring about gradual correction. If there is evidence that the percomorph liver oil is causing some renal irritation, it would be well to change to some other form of vitamin D. Massive doses are not indicated unless there is evidence of a real rachitic change in the bone. If the deformity is severe, osteotomy of the lower end of the femur or the upper end of the tibia, depending on where the malalignment is most evident, would be justifiable. It is impossible to state whether the knock knee tendency will improve or increase as the thigh lengthens without knowing more about what has caused it. In the average patient mild knock knee can be corrected, however, with the simple shoe correction in addition to a maintenance dose of vitamin D.

REHABILITATION OF THE DEAF

To the Editor:—I note in the St. Louis press the recent death of Dr. M. A. Goldstein. Dr. Goldstein established the Central Institute for the Deaf, in embryo, about twenty-five years ago. It has grown to be a successful school. I have been out of the practice of medicine for at least ten years and have not kept pace with the latest advances in restoring the hearing in those congenitally deaf or the victims of such resistant and intractable afflictions as otosclerosis or traumatic deafness. Will you please tell me just what supposed permanent advancement in otologic science Dr. Goldstein is credited with—whether physiologic, electric or mechanical? The St. Louis press leaves one to understand that originality and creativeness are involved in the methods in use in the institute.

M.D., Louisiana.

ANSWER:—Dr. Goldstein's interest and activities were directed chiefly toward the teaching and rehabilitation of the deaf person rather than to the treatment of deafness. He originated no methods of "restoring hearing in the congenitally deaf or in those afflicted with otosclerosis or traumatic deafness." His views on the management of the deaf child are expounded in Goldstein, Max Aaron: *The Acoustic Method for the Training of the Deaf and Hard of Hearing Child*, St. Louis, Laryngoscope Press, 1939.

CONTROL OF HEMORRHAGE AFTER TONSILLECTOMY

To the Editor:—I have heard that equal parts of gallic acid and tannic acid are good to control hemorrhage with after tonsillectomies. Is this true, and, if so, what strength of the two acids is used?

Joseph P. Sparks, M.D., Manila, Ill.

ANSWER:—It is true that gallic and tannic acids are useful in the control of hemorrhage after tonsillectomy. They should be used, however, only for the control of minor hemorrhage. Severe bleeding from large vessels should be handled as it is in other branches of surgery, namely by means of pressure, clamping and the ligature.

A 1 ounce medicine glass is filled with gallic acid or tannic acid crystals, separately or in equal amounts, and enough epinephrine hydrochloride 1:1,000 in physiologic solution of sodium chloride should be added, drop by drop, until a paste of the consistency of mustard is obtained. The whole should be stirred as it is prepared. Tannic and gallic acids are easily soluble in this solution and too much should not be used, as the mixture then becomes too thin for efficient action.

PREGNANCY AND MÉNIÈRE'S DISEASE

To the Editor:—A woman aged 29 has been under my care for Ménière's disease for the past one and one-half years. Treatment with a low sodium Fürstenberg regimen, ammonium chloride and the use of histamine sodium phosphate intravenously, as used at the Mayo Clinic, have been successfully employed. The patient has a child 5 years of age, having had a pregnancy five years ago that terminated normally and spontaneously. She is desirous of having another baby. Will this have a detrimental effect on the Ménière's disease?

M.D., New York.

ANSWER:—While any metabolic disturbance may cause an exacerbation of Ménière's disease, if the patient has been free from symptoms for some time there is not a great likelihood of trouble from pregnancy. Ménière's disease tends to run a self-limited course, and the patient may now be past the stage of severe attacks of vertigo.

TREATMENT OF ACUTE NEPHRITIS

THE IMMEDIATE RESULTS AND THE OUTCOME
TEN YEARS LATER IN EIGHTY-NINE CASES

FRANCIS D. MURPHY, M.D.

AND

BRUNO J. PETERS, M.D.

MILWAUKEE

If the problem of acute nephritis were limited in its scope to the acute episode, the subject would be a comparatively simple one. But this is not the case. While it is not unanimously believed that chronic glomerular nephritis evolves from an unhealed acute attack, this is an opinion widely held. During the past ten years observations by many investigators¹ have been made on the relationship of the acute phase to the chronic form, and there seems to be sufficient evidence to substantiate the assumption that chronic glomerular nephritis is a remote consequence of acute nephritis which failed to heal completely.

There are many obstacles in establishing the proper correlation between the acute and the chronic stage of nephritis. Among them is the difficulty of convincing the patient of the need of reexamination in the years after the acute phase is over and before symptoms of chronic nephritis begin. During the period of transition between the acute and the chronic stage the patient may appear and feel well and no medical attention may be considered necessary, yet the nephritis may be gradually destroying the renal units. Then too the physician who sees the patient years later, when the chronic form sets in, is apt not to be the one who studied him in the initial period of the disease. This is particularly true when acute nephritis occurs in children.

Not until recent years have methods been devised to determine the presence of a minimal unhealed lesion in the kidney. Before the method of Addis² was employed and prior to the use of such tests as determination of the sedimentation rate of the erythrocytes and the blood urea clearance test, the presence of latent nephritis was largely overlooked. It is in the latent

or transitional period, when the patient appears normal and seems cured but in fact is not, that the key to the correlation between acute and chronic nephritis is found.

In the last decade the number of after-studies of patients with acute nephritis has been growing steadily. These observations have been responsible to a large extent for the modern concept of acute nephritis, which is that not all the classic syndromes of hematuria, edema, hypertension and albuminuria are required before a diagnosis of acute nephritis can be made. Milder forms are being recognized and treated adequately in an increasing number of cases. Simple methods have been devised which aid greatly in determining whether the renal lesion has healed or is remaining active after the acute phase is supposedly over.

In reports dealing with the ultimate prognosis of acute nephritis great divergence of opinion is shown. Some authors³ have reported that complete recovery is the usual course, with chronic glomerular nephritis following only rarely, while others⁴ have expressed the belief that chronic nephritis is a fairly common consequence in later years. How statistics may vary in this regard is shown by Snoke⁵ in his follow-up study comparing the prognosis in a series of cases at Stanford University School of Medicine with that in a series at the University of Rochester School of Medicine and Dentistry.

ANALYSIS OF THE PRESENT SERIES

Our report is concerned with 205 patients with acute nephritis studied in the initial stages at the Milwaukee County Hospital and kept under observation for two to ten years afterward. The series includes both adults and children who were studied in the hospital for three months to a year and were observed at regular intervals at the outpatient clinic during the years that followed.

Our interest was focused particularly on 89 patients who recovered from the initial stage of acute nephritis satisfactorily but continued to have evidence of activity

From the Department of Medicine, Marquette University School of Medicine, and the Clinics, Milwaukee County Hospital.

of a renal lesion for months afterward. After discharge from the hospital, these patients were readmitted for study at regular intervals when it was thought advisable. Check-up examination included daily urinalysis of the twenty-four hour specimen, examinations of the urinary sediment by the method of Addis, blood urea clearance tests, determinations of the sedimentation rate, blood cell counts and determination of the blood pressure twice daily.

Chart 1.—Outcome in 205 cases of acute nephritis studied during a ten year period.

nation, but we assume rightly or wrongly that they remained in the state of recovery. The patients who died in the acute stage and those whose disease became chronic within a year, as well as those who did not return for reexamination having been eliminated, there are 89 whose careful follow-up study is the chief topic of this paper.

Forty-one, or 46 per cent, of these 89 patients were considered cured, but 6 later showed evidence of latent nephritis (charts 2 and 3). Forty-eight, or 53.9 per cent, had some evidence of renal inflammation (latent nephritis) at the time of discharge. Thirteen, or 27 per cent, of these continued to have latent nephritis. Fifteen had an excessive number of red blood cells in the urine. A follow-up study of these 15 showed that eventually 10, or 66.6 per cent, were healed completely and that the remaining 5, or 33.3 per cent, continued to have evidence of an active renal lesion. Of the group of 48, 18 were dismissed from the hospital with both albumin and an excessive number of red blood cells in the urine. Four, or 22.2 per cent, of them continued to show an active renal lesion. Fifteen of the 48 were discharged with a trace of albumin but no red blood cells or casts in the urine, and 4 of these, or 26.6 per cent, continued to show activity of the renal lesion. Therefore, when the ultimate result in the 205 patients is considered, there were 70 patients, or 34.1 per cent of the total series, with complete recovery, and 19, or 9.2 per cent, found on reexamination to have latent nephritis. Thirty-five, or 17 per cent, were discharged as completely cured but failed to return for reexamination. If these figures are corrected and the patients not returning for examination are excluded there is an amended figure of 41 per cent for patients completely healed. If the patients with chronic and those with latent nephritis are grouped approximately 36 per cent have an unhealed renal lesion. Also, if this figure is corrected to exclude the patients not returning for examination, a resulting 43.5 per cent of our patients still have an active lesion.

Age and Sex Distribution.—The age and sex distribution in 89 cases of acute nephritis is given in table 1 and chart 4, and this distribution is made the

object of a special study in table 2, in which 19 patients with nephritis in the latent stage are compared with the 70 cured patients who had acute nephritis. In our series 58 patients were male and 31 female. Of the 19 patients with latent nephritis 14 were male and 5 female. From table 1 it may be seen that most of our patients were adults, and in the greatest number the disease occurred between the ages of 10 and 20 years. In 14 it occurred between the ages of 20 and 30 and in 14 others between 30 and 40. It may be seen in table 2 that latency predominated in the group of patients aged from 10 to 20 years.

Etiology.—In tables 3 and 4 the diseases that preceded the acute nephritis in the 89 cases are listed. As in almost all other reports, infections of the upper respiratory tract constituted the chief offender. As far as we could make out, the type of preceding acute infection had little or nothing to do with the prognosis. Sometimes acute nephritis comes on within a few days of the onset of the preceding disease, but most often the first evidence of nephritis develops from seven to fourteen days after the onset of the acute infection. The period of lapse between the onset of the acute disease and the occurrence of nephritis appears to make little difference in the ultimate outcome.

THE CLINICAL COURSE

No attempt was made to classify our cases into various groups according to the intensity of one clinical feature or another. We believe that there is but one acute nephritis and that there is no advantage in further subdividing the series. Acute nephritis may develop abruptly, displaying all the classic textbook features, such as hypertension, edema and hematuria, or it may come on so insidiously that it may escape notice entirely unless the urine is examined and evidence of renal involvement found. The mild type seems innocent at first, but the benignity is more apparent than real, for the ultimate outlook for the patient with mild nephritis is no better than that for the patient with a more severe form of the disease.

The clinical manifestations of acute nephritis may be few or many. In our study we have classed these clinical features in five main syndromes and have studied them routinely in each case. They are (a) the urinary syndrome, (b) edema, (c) hypertension, (d) retention of nitrogenous products in the blood and (e) uremia, genuine or convulsive. These syndromes all may be present in a patient at the same time, or one syndrome may occur, dominate the clinical picture for a brief

Chart 2.—Condition of 89 patients at time of discharge.

period and then disappear entirely, only to return at a later period or perhaps never to return. In table 5 the various syndromes are listed and the combination of them appearing in the 89 cases is given. The number of times that each syndrome occurred is incorporated in table 6.

(a) *The Urinary Syndrome.*—The urinary syndrome occurred alone in 25 instances and it was present in every one of the 89 cases. A simple, careful study of the urinary syndrome is without doubt most important, because its significance is least likely to be misinterpreted and it is present in every case. The occurrence of the urinary syndrome alone is worthy of more

Chart 3.—Data on urine in 89 cases at time of discharge.

thought, because often the examination of the urine is neglected unless other evidences, such as hypertension, edema and hematuria are found. Some cases of acute glomerular nephritis have been reported⁶ in which albuminuria was absent for a time after other evidences, such as hypertension and edema, appeared. We did not observe such cases in this series.

(b) *Edema.*—Although edema in acute nephritis may result from heart failure as well as from the nephritis, our figures for the incidence of edema in acute nephritis refer entirely to renal edema and not to the kind that comes from heart failure. Edema marks the onset of acute nephritis in some cases. Its importance lies to a large extent in the fact that it serves to bring to the attention of the medical attendants of the patient the possibility of a renal lesion or involvement of the kidney. Although some observers look on edema as a grave sign, usually it is innocent. We failed to find that patients with edema fared worse than patients without it. This statement does not hold for the edema that occurs in the period following the first few weeks of acute nephritis. When edema develops after the first weeks, it usually signifies that the nephritis is going into the degenerative or subacute or chronic phase, and its prognostic significance is important. Edema alone with the urinary syndrome occurred 11 times, and of 89 cases edema was present in 42.

(c) *Hypertension.*—Of 89 cases, hypertension occurred in 33. It was the only syndrome besides the urinary syndrome in 6 cases. Formerly hypertension was considered a constant feature of acute nephritis, but this idea is no longer held. Hypertension may be lacking throughout the entire course of the disease. Its onset in the course of acute nephritis, however, is significant. Although the patient with acute nephritis may progress unfavorably without hypertension, its onset is always a discouraging and sinister event. When

hypertension develops in the latent stage of nephritis, as it often does, the chances of complete healing may be given up in almost every case.

(d) *Nitrogen Retention.*—Elevation of the nonprotein nitrogen content occurred in 30 cases and alone with the urinary syndrome in 8 cases of the 89. In the early period of acute nephritis a rise in the blood urea nitrogen level is of little significance, but when it occurs after the first ten days its presence causes great concern, because it indicates that the kidneys are not functioning as well as they were in the beginning, and the prognosis becomes doubtful. As a guide in the diagnosis of acute nephritis a study of the blood urea nitrogen content is not important, but as a prognostic indicator it is useful after the first ten days or two weeks of the disease.

(e) *Uremia.*—Genuine uremia occurred two times without any of the syndromes other than the urinary syndrome. Genuine uremia is the direct outcome of renal insufficiency and is entirely independent in origin of the convulsive seizures which may be associated with it. A rise in the blood urea nitrogen level is the precursor of uremia in most instances, and it is involved in the development of this syndrome. Any condition which interferes with the urinary output may lead to genuine uremia. The convulsive seizures may occur in connection with genuine uremia but are not dependent on renal insufficiency. The convulsions are associated with edema of the brain and usually are precipitated by acute hypertension. In 2 cases in this series convulsive seizures occurred without hypertension, but in most instances a diastolic pressure of 120 mm. of mercury, edema of the optic disks, fresh hemorrhages and fluffy white patches accompany convulsions. The pressure of the spinal fluid in convulsive uremia is usually increased from the normal of 150 mm. of water to 300 mm. While patients in whom genuine uremia develops hardly ever recover, it cannot be said that they never do so. The outlook is entirely different with the so-called convulsive type of uremia, which frequently clears up and appears to have little or nothing to do with the chances of a rather long life afterward. The prognosis of uremia, whether genuine, convulsive or compound, depends on the functional ability of the kidney and the persistence of the hypertension rather than on any one of the other numerous signs and symptoms.

PROGNOSIS AND THE LATENT PERIOD

After the acute episode is over, whether it is mild, moderate or severe, there is a variable period of two

months to two years in which some patients appear well but on careful examination of the urine show evidence of an inflammatory lesion in the kidney. This is called the latent period. It is characterized by a complete absence of clinical evidence of nephritis and

Chart 4.—Distribution according to sex of 89 patients with acute nephritis. Shaded area represents patients who went into a latent stage.

6. Fishberg, A. M.: *Hypertension and Nephritis*, ed. 3, Philadelphia, Lea & Febiger, 1934, p. 468.

by albuminuria and an excessive number of red blood cells, white blood cells and granular casts in the urine. It is an important phase of the disease, because during it the ultimate fate of the patient is often determined. Lack of proper consideration of this symptomless period

TABLE 1—Age and Sex in Eighty-Nine Cases of Acute Nephritis Followed for One to Ten Years

Age Group	Male	Female	Totals
0 10.	18	4	22
11 20	25	11	36
21 30	5	9	14

41 50	1	1	2
51 60	0	1	1
Totals	58	31	89

was considered by Snoke⁵ to be responsible for conflicting views on the prognosis of acute nephritis. To this opinion we readily subscribe, as our previous observations⁴ showed that failure to interpret data correctly in this period leads to faulty conclusions.

In this period of transition the kidney may gradually heal completely or the disease may progress into chronic nephritis. It may be difficult to say when the latent period is over and chronic nephritis begins, as the latent phase may merge gradually with the chronic form, but usually after two years the disease may be classed as chronic. Addis,² who was the first to study this latent phase adequately, observed that patients may remain in it for as long as ten years apparently in perfect health but always with an abnormally high number of red blood cells and a few blood casts.

More rigid adherence to the rules of treatment at this time may accelerate complete recovery, while laxity may retard healing. It is difficult to determine whether the renal lesion is healing or becoming chronic. The tests of renal function usually employed are insufficient for this purpose. It is essential to determine the degree of activity of the lesion in the kidney and by repeated examinations to observe whether healing or inflammation is gaining the ascendancy.

TABLE 2.—Age and Sex of Nineteen Patients with Latent Nephritis and of Seventy Patients Cured of Nephritis

Age Group	With Latent Nephritis		Cured	
	Male	Female	Male	Female
0 10.	1	1	17	3
11 20	9	3	16	8
21-30	1	1	4	8
31-40.	2	0	7	5
41 50.	1	0	0	1
51 60	0	0	0	1
Totals	14	5	44	26

Several methods have been used in obtaining this information, and we believe that a combination of the results of these tests forms a better prognostic guide than the results of any one test taken alone. To learn which course the disease is taking in a given case requires more than a single examination. Reliable data are dependent on these tests done not once but many times. We have employed the following procedures in most of our cases, and while not all the tests are

of uniform importance we believe that all are good prognostic aids.

1. A count of the casts and cells in the urinary sediment by the method of Addis was the greatest aid of all. This test was done at regular intervals, depending on the nature of the case.

2. A study of the ability of the kidney to concentrate urine (Volhard's method) was found reliable. Progressive impairment of concentration pointed to a progressive unhealed lesion.

3. The blood urea clearance test has been used regularly in our cases, and we believe it has been helpful. When the urea clearance is low at the beginning and improves in time the outlook for the patient is good, but when repeated examinations show a tendency toward a drop in the percentage the outlook is unfavorable.

Ruptured appendix	1
Undetermined cause	1

4. While not a basis for determining precisely the progress of the renal lesion, anemia that fails to respond satisfactorily to ordinary therapeutic measures, such as the administration of iron and vitamins, indicates that the renal lesion is probably becoming worse.

5. Estimations of the plasma proteins are important prognostically even though the plasma albumin does not drop to the critical level of 2 Gm. per hundred cubic centimeters. It is important to remember that a lowered plasma albumin content, for example 3 Gm. per hundred cubic centimeters, and a value for total protein of less than 5 Gm. per hundred cubic centimeters point to an unfavorable prognosis.

6. Finally, we have come to look on determination of the erythrocyte sedimentation rate as a valuable aid in prognosis (chart 5). While we cannot say that it is always accurate as a prognostic measuring stick, it nearly always is. We have employed this test for fifteen years in our clinic, and we believe that in general a rapid sedimentation rate indicates that an unhealed lesion is becoming progressive. A slowing down of the sedimentation rate points to a subsidence of the inflammation, while a normal rate points to a healed or almost completely healed lesion.

TREATMENT

That rest is valuable for the patient in general and for the kidney in particular is the first principle in the treatment of nephritis. In this paper we are concerned primarily with the treatment of the patient after

the acute stage is over. Our results, especially in adults, emphasize the importance of keeping the patient in bed for several months if necessary after the clinical features have passed and until the last remnants of nephritis have disappeared. In chart 3 it may be seen that the 41 patients who were cured were those who remained in the hospital until well and that the 48 who left the hospital before cure was accomplished fared less well eventually. We grant that such prolonged enforced rest may be difficult in some cases because occasionally younger patients, their parents and unfortunately the medical advisor fail to recognize the need of it. But the end does justify the means in these instances. We enforce modified bed rest for four months; we believe that after this rigid adherence to inactivity fails to accomplish our purpose, since a chronic condition probably has set in, and rest is no longer enjoined.

Physical inactivity serves to obtain rest for the circulation, lessens the demand for food and metabolic activity and materially reduces the work of the crippled kidney. Rest for the kidney in particular is accom-

TABLE 6—*Incidence of Syndromes in Eighty-Nine Cases of Acute Nephritis*

Number of cases	89	33	42	30	3	8

plished by regulation of the diet. This must not be taken to mean that the diet is inadequate. The daily protein intake should range from 0.75 to 1 Gm. per kilogram of body weight. Some patients may do well with less, and others may do better with a larger amount of protein. Protein starvation may spare the kidneys at the expense of the economy of the body in general, which is as bad as giving too much protein and retarding recovery of the renal units. From the experimental

work of Addis,⁷ Farr and Smadel⁸ and Chanutin and Ferris⁹ we note that the injured kidney heals faster when a low protein diet is given and slower or not at all when a high protein diet is given. The relative rest for the kidney conferred by a low protein diet is the factor considered important. Although experimental observations cannot be transferred wholly to clinical practice, reports from many quarters of good results with a low protein diet tend to substantiate this impression. Yet other investigators have expressed the belief that a high protein diet is not injurious to patients with acute nephritis. Keutmann and McCann¹⁰ found that a high protein diet did not retard healing and that the return of renal function was accelerated. Naeraa¹¹ followed a number of patients with acute nephritis, making Addis counts, and came to the conclusion that a high protein diet is not harmful to the kidney. Mosenthal¹² and Cameron¹³ both expressed the belief that a strictly low protein diet does not spare the kidney and that judging from their experience there is no need to fear that protein is injurious to the kidney

CHART 5—Sedimentation rate of 89 patients with acute nephritis

in nephritis. Protein starvation, they said, is more likely than protein excess to harm the patient.

We believe that our diets containing 0.75 to 1 Gm. of protein per kilogram of body weight represent neither starvation nor an excess of protein but fulfil the protein requirements of the patient adequately and yet do not retard healing.

We¹⁴ compared the high acid ash diet and the high alkaline ash diet in a series of cases of acute nephritis

and found that as far as healing in the early stages is concerned there appears to be little or no difference. In cases of latent nephritis in which treatment is continued over longer periods the results are about the same as those mentioned.

The problem of giving salt and water during the healing phase is not a difficult one. Simple restriction of sodium chloride to an average quantity of 5 to 6 Gm. daily is sufficient. The intake of fluid should be tempered according to desire, but excesses should be guarded against. As to vitamins, it is essential to give sufficient amounts of A, the B complex, C and D. These are easily given before meals. While it is difficult to prove satisfactorily that the administration of iron is advantageous, in practice it has been shown to be helpful.

The theory advocating the removal of foci of infection in the treatment of nephritis has lost some of its popularity, but we believe such foci should be removed. Diseased tonsils, foci of infection in sinuses, apical abscesses or abscesses anywhere should be removed about one month after the passing of the acute episode. While statistics may fail to provide evidence of the benefit of such removal, the individual patient often shows striking benefit.

COMMENT

The ultimate prognosis rather than the immediate outcome of acute nephritis has been our chief interest for some time. Why some patients who have recovered from acute nephritis are completely healed and others progress gradually into the stage of chronic nephritis is an unsolved problem. There seem to be some factors, however, which influence the course of the disease. In our review of the cases in this series we have attempted to determine what factors accelerated or retarded the complete healing of the renal lesion.

We were impressed particularly by the fact that the lesion which failed to heal immediately tended to do so eventually if rest and careful attention to simple regulations of treatment were adhered to.

The acute phase of nephritis was observed to be the forerunner of the chronic form in a sufficient number of cases to convince us that the relationship is more than coincidental. We believe that the failure to understand the significance of the latent phase is one of the main stumbling blocks in the recognition of the relationship between the acute and the chronic form. Rigid adherence to the regimen of rest when there is even slight activity of the renal lesion helps bring about complete recovery. The intensity of the initial stage of acute nephritis has little or no bearing on the ultimate outcome, but the duration of the disease which precipitates the acute nephritis may often have an effect on the ultimate outcome of the renal lesion. While in itself the age of the patient is probably not an important factor in prognosis, in our series the persons aged 10 to 20 years got along less well than those in the other age groups. The retarding of recovery is due not so much to the age as to the fact that patients at this time of life are more difficult to control and are less amenable to treatment.

The prognosis in various series of cases depends on factors that are not often mentioned. For example, patients in a large charity hospital are apt to be admitted for treatment after a delay of some weeks

following the onset of the acute stage. It is more difficult to convince patients who come to such an institution of the importance of rigid treatment when they feel no pain or distress of any kind. Judging from Snoke's⁵ comparative study of cases in San Francisco and in Rochester, N. Y., it may be said that the geographic location may be one of the deciding factors in prognosis.

Many reports have shown a uniformly good prognosis in acute nephritis. Ludbrook¹⁵ stated that 97 per cent of the 60 patients with acute nephritis in his series followed from one to six years were entirely cured at the time he wrote. Aldrich,¹⁶ Blackfan,³ Richter⁴ and Tallerman and Burkinshaw³ expressed the view that most patients make a complete recovery. In an after-study of acute nephritis among soldiers in the first World War, Keith and Thomson¹⁷ gave a favorable report concerning the ultimate outcome; yet they emphasized that the prognosis as to complete recovery must be guarded.

Our observations, both of the present and of former series,¹⁸ do not support the contention that nearly all patients with acute nephritis recover completely. Still,¹⁹ Snoke,⁵ and Folkers²⁰ have reported series of cases in which the ultimate outcome was not favorable. Longcope²¹ followed 134 patients for one to fourteen years and reported 42.5 per cent with healed, 33 per cent with latent and 11.2 per cent with chronic nephritis, while 14.2 per cent had died.

SUMMARY

1. Of 205 patients with acute glomerular nephritis observed from two to ten years, including both adults and children but mostly adults, 55, or 26.8 per cent, acquired chronic nephritis; 26, or 12.6 per cent, died in the acute stage, and 19, or 9.2 per cent, entered the latent stage. Thirty-five, or 17 per cent, although clinically cured at the time of discharge did not return for reexamination. Seventy patients, or 34.4 per cent, were completely cured. Correcting these figures to exclude the patients not returning for examination, we have an amended figure of 41 per cent for patients completely healed. If we group the patients with chronic and those with latent nephritis, approximately 36 per cent have some evidence of renal involvement; similarly, if this percentage is corrected 43.5 per cent of our patients still show latent or chronic nephritis.

2. The prognosis was found to be no better when the initial stage was mild than when it was severe or stormy.

3. The latent period is significant and should be emphasized, for in it the ultimate fate of the patient is often determined.

4. We do not believe that the prognosis of acute nephritis is as favorable as many investigators have reported.

ABSTRACT OF DISCUSSION

DR N M KEITH, Rochester, Minn. Drs Murphy and Peters' statistical results of cured cases are very similar to those of Hume and Nattress, who followed up cases of acute trench nephritis of the soldier after the great war in Newcastle, England. They found that of some 280 patients about 45 per cent were cured after a period of several years. Dr Longcope of Baltimore has also reported about the same number of cured cases in his series. That is an important fact and I believe that Dr Murphy and all of us will agree that we must and can have a larger percentage of cured cases. Apparently a great many of these patients leave the hospital too soon and after dismissal do not get the care they should. I think it is important, as Drs Murphy and Peters pointed out, that we must do our best in the latent stage to be sure that these patients are not still suffering from the disease. Dr Addis, I think, has done us a great service by instituting his test of counting the number of red cells present in the urinary sediment of these patients. Drs Murphy and Peters have mentioned the removal of foci. I believe, like Dr Longcope, that when there is an active focus it should be removed and, if possible, after the acute renal episode has subsided. Drs Murphy and Peters stated that they like to keep these nephritic patients in bed for four months. I do not think that there should be any arbitrary fixed rule, however, I believe it is better to err on keeping the patients too long than too short a time in bed. A patient of mine, a young man with acute nephritis with severe albuminuria, hematuria and hypertension, was given a diet such as the authors advocate. This man was an orderly in our hospital. We were thus able to watch him carefully and keep him in the hospital for approximately two months. He did well. It is eighteen months since his initial attack. What I want to bring up is that I am not certain yet that he is cured. He will have to be observed further, in spite of a normal urine, for albuminuria and hematuria, eighteen months after the initial attack of acute nephritis.

DR MOSES BARRON, Minneapolis. I agree with nearly everything the authors say in their paper on nephritis. Their statistics parallel those in the better clinics of the country. They quoted some authorities who give higher percentages in recoveries, some as high as 96 per cent. I think those high figures occur as a result of errors in diagnosis. Undoubtedly the milder forms of focal nephritis following many acute infections which usually go on to complete restitution are included in those statistics of glomerular nephritis. A much smaller percentage of cases of acute nephritis following scarlet fever pass into the latent or chronic state, probably only 5 or 7 per cent instead of 30 or 40 per cent. In acute diffuse glomerular nephritis about 10 per cent die in the acute stage. Death is due to acute infection, otitis media, pneumonia, uremia and occasionally heart failure. I wish to emphasize the importance of watching cases of nephritis for heart failure, since digitalis may prove life saving. The poor circulation from a failing heart may throw a not severe renal insufficiency into a fatal uremia. The first three or four days' diet should consist of a little fruit, orangeade, lemonade and a restricted fluid intake to a total of 300 to 500 cc. For the next few days a little more fruit and fluid may be added. Later small amounts of protein, starches and fats are gradually added until the proper caloric intake is provided. The protein should be increased to not more than two thirds of a gram of protein per kilogram of body weight. I agree with the authors that excessive protein in the diet is deleterious during the acute stages of nephritis. An increased amount of protein means increased work for the kidneys and this leads to greater damage to the already diseased kidneys. One must differentiate between hypertensive encephalopathy and true uremia which may accompany advanced stages of nephritis. The treatment of these two conditions is entirely different. Uremia is always associated with the retention of metabolic products in the blood as a result of renal insufficiency. The blood pressure in some instances may be normal. In hypertensive encephalopathy the blood chemistry may be entirely normal but the blood pressure is always greatly increased. The treatment of hypertensive encephalopathy is venipuncture, spinal puncture, magnesium sulfate by mouth and intravenously, and the prevention of convulsions by restriction of fluids and the use of morphine if necessary. I believe that treatment of

glomerular nephritis is most important in the acute stage. During the latent period there is little that one can do except advise against chilling. One cannot keep patients at absolute rest all the time. They should be watched for the first signs of an exacerbation and then again be subjected to the treatment applied in an acute case.

THE LOCAL USE OF SULFANILAMIDE
IN THE TREATMENT OF PERI-
TONEAL INFECTIONS

R STERLING MUELLER, MD

AND

JAMES E THOMPSON, MD

Assistant Attending Surgeons, Roosevelt Hospital
NEW YORK

Two years after the report of Domagk¹ in 1935 concerning the chemotherapeutic properties of azosulfamide, certain bacterial infections were commonly treated with sulfanilamide with excellent results. Given by mouth, by rectum or by hypodermoclysis at regular intervals, therapeutic blood and tissue concentrations could be maintained which had a definite bacteriostatic effect on certain organisms. In April 1937 Sinclair and Barker² departed radically from the usual plan of administration of sulfanilamide and for the first time made use of high local concentrations of the drug for the treatment of localized infections. They used crushed sulfanilamide tablets in dental surgery, such as for infected operative wounds in the mouth, certain extractions, compound fractures and osteomyelitis of the mandible—with good results in the prophylaxis and treatment of infections. In July 1939 Jensen, Johnsrud and Nelson³ reported a series of compound fractures treated with local implantation of sulfanilamide. In this series no instances of primary infection occurred. Other reports of its local use followed shortly and it soon became evident that, if proper amounts of the drug were used, toxic levels in the blood did not occur. On Jan 10 1940 sulfanilamide was first used intraperitoneally at the Roosevelt Hospital⁴ in a desperate attack of diffuse peritonitis. This critically ill patient made such a dramatic and unexpected recovery that it was used in other similar abdominal conditions with equally good results. Within a short time in this hospital the local use became a routine procedure in all kinds of infections or contaminated peritoneal conditions.

With the use of sulfanilamide locally, either in soft tissues or in body cavities, local concentrations from seventy-five to one hundred times higher than systemic concentrations may be obtained directly at the source of the infection. Furthermore, with proper amounts of the drug, absorption into the blood or tissue fluids does not exceed safe therapeutic levels, and no injurious action in tissues exposed to the concentrated drug is seen. Such high concentrations naturally have a higher bacteriostatic effect than the usual blood levels. We feel, from clinical observation, that even more organisms

Dr John A. Bralton helped with the statistics used in this paper.
Read before the Section on Surgery, General and Abdominal, at the Ninety Second Annual Session of the American Medical Association, Cleveland June 4, 1941.

may be effected and that the action of the drug approaches that of a bactericidal agent. In many ways sulfanilamide compounds used locally are ideal tissue antiseptics in that they seem to have a low toxicity for tissue unlike other presulfanilamide compounds.

Fig. 1—Lower half, microscopic view of sulfanilamide crystals. Upper half, microscopic view of peritoneal exudate from patient, post mortem, in which the spaces occupied by the crystals may be seen.

We have continued to use the parent compound sulfanilamide rather than its derivatives sulfapyridine, sulfathiazole and sulfadiazine in all our peritoneal cases—first, because we began with that particular drug and have had no unpleasant experiences with it in the peritoneal cavity; second, because more is known about the fate of sulfanilamide in the human body in regard to its absorption, toxicity and excretion, and finally, because many patients must be treated with these compounds before the clinical observations and experimental investigations can be evaluated for that particular drug, in regard to its place as an adjunct to the surgical care of peritoneal infections. Sulfathiazole may be used instead with good results. In cases of abscess equal amounts of sulfanilamide and sulfathiazole may be used in the abdominal cavity and elsewhere. We are trying this combination at present.

STERILIZATION OF SULFANILAMIDE POWDER

The most suitable container for sulfanilamide powder is a sterile test tube in which the drug is placed in weighed amounts and sterilized. It is convenient to have amounts of 2, 4, 6 and 8 Gm. available in the operating room. The tubes are stoppered with a cork or cotton and then further sterilized by means of dry heat for two hours at 140 C. This causes no change in the crystalline powder. The other sulfanilamide compounds may be sterilized in the same way. The drug may also be autoclaved if moisture is not allowed to reach the powder, but if moisture does reach the

drug during sterilization the powder is converted into a solid mass which cannot be removed from the tube and is unfit for local surgical use. Sulfanilamide may also be obtained in sterilized form in ampules. However, it is not as easy to sprinkle the drug into the peritoneal cavity from the narrow necked ampules as from uniform width test tubes. It was difficult in the first few cases to determine the proper and safe amount of the drug which should be used. It so happened that we had been using 10 to 15 Gm. of sulfanilamide locally elsewhere in the body in compound fractures and in large dirty traumatic wounds. Therefore, in the first case about 12 Gm. was used. Since blood levels, taken postoperatively in this case, were within safe therapeutic limits, we felt that it was safe to continue to use about this amount. Infections of lesser degree require less of the drug. In peritoneal infections of very severe involvement, or when massive soiling of the peritoneal cavity has occurred, we have not hesitated to use even larger amounts. A total dose in the peritoneal cavity alone should never exceed 15 Gm. The cases in which drainage is established require more of the drug locally than those in which the cavity is closed without drainage, since a certain amount of the drug is lost through drainage.

Of the total amount of sulfanilamide used in any 1 case, two thirds is placed in the peritoneal cavity and the remaining third is sprinkled in the layers of the abdominal wall. Placing some of the drug in the

Fig. 2—Microscopic view of sulfanilamide crystals in peritoneal exudate of rabbit forty eight hours after operation.

abdominal wall has, without question, increased the rapidity of wound healing in cases of purulent infection. There is no doubt that involvement of the wound seems more limited and localized in the vicinity of the emerging drains. This has been such a consistent finding that in some of the cases of frankly purulent infection

we have closed the wound around the drains rather than suturing the peritoneum only and leaving the other layers unsutured. In many cases of peritonitis drainage of the peritoneal cavity could be eliminated with the use of sulfanilamide powder, but we believe that this is generally unwise. At least for the present the old rule "when in doubt, drain" should be followed

Fig. 3.—Computed average blood level curve.

as it was before the use of this drug. There are many cases of peritoneal infection not severe enough to justify the use of sulfanilamide in the peritoneal cavity but in which it is good practice to use 2 to 4 Gm. in the layers of the abdominal wall only. This will prevent or lower the incidence of infection in moderately contaminated wounds.

In very young children and infants the total dose of sulfanilamide used in the peritoneal cavity and abdominal wall should not exceed 3 to 4 Gm. Since age and weight modify the dose, it is safe to calculate the dose on a basis of 175 mg. per kilogram of body weight, after one has taken into consideration the degree of infection or contamination present.

TECHNIC OF LOCAL USE

The powdered drug is sprinkled into the peritoneal cavity as near the focus of infection as possible. This is considered a better method than that of depositing the drug in a mass in one place only, as we had formerly done. When no focus of infection has been found or when the patient is too ill to permit its removal, the powdered drug is deposited over the peritoneal surfaces beneath or adjacent to the incision. If the drug is deposited in one mass, where it remains in prolonged contact with a serosal surface, a local hemorrhagic area covered with fibrin may occur. There is no evidence in our series of cases that any harm has resulted because of it being used in this manner. It is usual for some hyperemia to occur in the immediate region where the sulfanilamide comes into contact with the peritoneum, but this lasts only for a short time. A moderate amount of serosanguineous discharge escapes from the drain during the first thirty-six hours after the operation. In cases in which a postmortem examination has been made three or more days after the operation, fluid is not found in the peritoneal cavity and no trace of hyperemia is seen. Before the drug is placed in the abdominal cavity clamps should be applied to the peritoneum preparatory to its being sutured, since the powder may obscure the field.

In the lower half of figure 1 a microscopic view of the sulfanilamide crystals is shown. In the upper half is a section of peritoneal exudate in which the spaces occupied by the crystals may be seen. This section was

taken from a patient operated on for peritonitis from diverticulitis of the colon and who died of lipid pneumonia. The small number of cells in the meshwork of fibrin around the crystals indicate the absence of irritative action of the sulfanilamide. Figure 2 is a similar section from the peritoneal cavity of a rabbit. The original photographs are the property of the department of pathology of Columbia University College of Physicians and Surgeons.

There is no clinical evidence that sulfanilamide used locally has any deleterious effect on catgut used in the abdominal wall or in the peritoneal cavity. We have not noticed any interference with wound healing; on the contrary, infected or contaminated wounds have healed with great rapidity, as compared with similar wounds not treated with the drug.

ABSORPTION OF SULFANILAMIDE

Postoperative blood levels have been taken in nearly all our cases and, in 20 cases, level determinations have been taken at frequent intervals. Sulfanilamide is rapidly absorbed from peritoneal surfaces. As soon as twenty minutes postoperatively blood levels of 2 to 3 mg. per hundred cubic centimeters have been observed. While the initial rise is rapid and fairly consistent, the fall in the blood level is much more gradual but shows the same consistency (fig. 3). The peak of the blood level is reached in from ten to eighteen hours and averages 7 mg. per hundred cubic centimeters. At the end of one hundred and seventy-five hours, in undrained wounds, levels from 0.5 to 1 mg. per hundred cubic centimeters are found. As a rule, after two hours no trace of sulfanilamide is found in the blood. In cases in which drainage is instituted the height of the initial rise is lower and the blood level falls more rapidly.

It must be remembered that absorption is occurring from two different places and two different kinds of tissue, i. e. the peritoneal cavity and the operative wound. The drug is absorbed less rapidly, and for a longer period, from the abdominal wall than from the

Fig. 4.—Sulfanilamide levels in drainage fluid of a patient with appendical abscess.

peritoneal cavity. When the sulfanilamide is used in the peritoneal cavity alone, and not in the abdominal wall, the fall of the blood level to zero takes place in from seventy-five to one hundred hours.

Draper and Kauer⁵ have shown that after the intra-peritoneal application of sulfanilamide in dogs the blood

5. Draper, J. W., and Kauer, J.: Personal communication to the author.

level reached its peak in about six hours and rapidly approached zero in from sixty-five to seventy-five hours.

We mention these blood levels and absorption rates of sulfanilamide only as an indication that the drug is not absorbed into the system in toxic amounts. The greater the amount used, and the less it is allowed to

TABLE 1.—*Acute Appendicitis Series: 1935-1939*

Type	Cases	Deaths	Mortality, per Cent

* An additional death was discovered in this group after previous publication of this table.

be lost through drainage, the higher the possible blood level. Unless infection is present elsewhere outside the peritoneal cavity, the systemic concentration of the drug is of secondary importance only. The high levels, from 300 to 800 mg. per hundred cubic centimeters, that we have been able to obtain from samples of peritoneal fluid for more than forty hours postoperatively cannot be produced by the administration of any other form of the drug and are the active factors in controlling the peritoneal infection. We are unable to say at present whether the fall in peritoneal concentrations parallels the fall in systemic levels (fig. 4).

An analysis of acute appendicitis at Roosevelt Hospital during the five year period 1935-1939 is used as a background against which we hope to contrast our results since using sulfanilamide.

There was a total of 742 cases of acute appendicitis during the 1935-1939 period. In an analysis of such a series of cases certain criteria must arbitrarily be chosen to classify the various types of lesions so that they may be easily and clearly understood as well as easily and accurately compared with similar groups. It is for this reason that we eliminate the many confusing terms and classify acute appendicitis in the following manner.

Group 1.—Simple acute appendicitis. Here there is no gross perforation, and culture of fluid, if present, shows no growth. There were 566 cases of this variety with 3 deaths, a mortality of 0.53 per cent.

TABLE 2.—*Analysis of Deaths: 1935-1939*

	Deaths
Diffuse peritonitis	13
Postoperative pneumonia	2
Pylephlebitis and septicemia	2
Pulmonary embolism	1
Rheumatic heart and decompensation	1
Acute purulent cystitis	1
Total..	21

Group 2.—Acute appendicitis with localized abscess formation. There were 59 of this variety with 4 deaths, a mortality of 6.78 per cent.

Group 3.—Acute appendicitis with peritonitis. This final group includes both cases of spreading or diffuse peritonitis and those of the localized variety. It is believed that it is impossible to obtain a true knowledge of the extent of peritonitis through a McBurney incision, which was used in more than 95 per cent of our cases. The impression would vary with the individual surgeon and could be accurately determined only after an exploratory operation. There were 117 such cases with 14 deaths, a mortality of 11.96 per cent.

The total number of deaths was 21 in the three groups, giving a total mortality of 2.83 per cent. A fuller analysis of these deaths can be obtained from glancing at table 2, but needless to say the majority was directly attributable to peritonitis.

In January 1940 we began to use sulfanilamide in cases of severe appendicitis. The first few patients were desperately ill, the peritonitis in each instance seemed diffuse in character and the fluid was frankly purulent and had a fecal odor. The convalescence and cure of these patients was so dramatic that one could not help but be impressed with the value of the drug used in this manner.

A review of our past experience in the bacteriology of acute appendicitis with abscess formation and peritonitis showed that *Bacillus coli* was the predominant organism in 83 per cent of the cases. Other organisms encountered as etiologic factors in their order of frequency were gamma streptococcus and beta streptococcus. Sometimes associated with *B. coli* or with the streptococcus organisms were *Bacillus lactis aerogenes* and *Bacillus mucosus capsulatus*. No anaerobic cultures were taken.

TABLE 4.—*Cases of Acute Appendicitis (January 1940-May 1941)*

Type	Cases	Deaths
Acute..	201	0
Abscess..	23	0
Peritonitis	44	0
Total	268	0

We have noticed no definite toxic effects except some cyanosis, which, though not a constant feature, is usually evident. The nausea and vomiting, if present, have not been sufficiently distinguishable from that to be expected in a patient convalescent from any operation.

There have been no cases of leukopenia or acute agranulocytosis, but there was 1 case of jaundice which was felt to be secondary to infection, as it disappeared under continued administration of sulfanilamide by mouth.

Persistent elevation of temperature did occur in a few instances, and in several of these cases it was felt to be directly attributable to the sulfanilamide.

In those patients in whom sulfanilamide was used, the ages ranged from 1 year to 75 years. The lesion in 45 per cent of the peritonitis group could definitely be considered diffuse. Many of these patients were critically ill; in a few instances the condition of the patient and the local conditions presented a hopeless picture.

From January 1940 to May 1, 1941 we operated on a total of 268 patients with appendicitis and its complications. There were no deaths in any one of the three varieties of the disease. Sulfanilamide was used in a total of 90, or 33.6 per cent, of the cases, representing the most severe varieties of the disease. In 16 of these 90 instances the administration of the drug was continued either by rectum or by mouth, because of the

extremely severe pathologic process encountered at operation or because of the continued critical condition of the patient. The added experience with dosage has led us to believe that a sufficiently large intraperitoneal application might eliminate the necessity for any continued postoperative administration.

TABLE 5—Comparison of Important Complications

Type of Complication	1935-1939 (741 Cases)		Jan. 1, 1940 to April 1, 1941 (250 Cases)	
	Number	Percentage of Total Cases	Number	Percentage of Total Cases
Wound complication . . .	85	11.5	13	5.2
Secondary peritoneal abscess	21	2.8	2	0.9
Atelectasis	16	2.1	7	2.8
Pneumonitis	12	1.6	0	0
Wound separation . . .	8	1.1	0	0
Phlebitis	5	0.7	1	0.5
Pylephlebitis	2	0.27	0	0
Jaundice	1	0.13	1	0.5

Complications were relatively few in the total series, and there was a noticeable reduction in wound infections and secondary peritoneal abscesses as compared to the previous years.

It has been used in other peritoneal infections as a therapeutic agent, but to evaluate its relative importance in lowering the mortality rates in these specific conditions will take time. A thorough comparative analysis of large numbers of cases within each group will be necessary before any conclusions can be reached (table 6).

We urge its use in cases in which there has been extensive soiling from perforated peptic ulcer, particularly in those instances in which the perforation has existed longer than twelve hours. It has seemed successful in diverticulitis, perforations of the intestine, gunshot wounds, acute biliary surgery, complete hysterectomy, certain cesarean sections and other similar conditions.

In cases of acute salpingitis in which operation was performed on the basis of a mistaken diagnosis, it caused an unusually smooth and rapid convalescence.

The dose employed in these cases has been on the same basis as that recommended in the treatment of appendicitis.

TABLE 6—Intra-Abdominal Application of Sulfanilamide (Exclusive of Acute Appendicitis)

	No. of Cases	Deaths
As a prophylactic measure in abdominal surgery	90	8
As a therapeutic measure for peritonitis or abscess	21	6
Total	111	14

We are using it more and more frequently in elective surgery of the gastrointestinal tract, as a prophylactic agent, when actual or suspected soiling of the peritoneal cavity has occurred and when sulfaguanadine has not been used preoperatively. The dose under these circumstances has been considerably less, varying between 2 and 8 Gm.

SUMMARY AND CONCLUSIONS

Sulfanilamide is recommended for use intraperitoneally when any form of peritonitis is encountered at operation.

Its use in routine abdominal surgery when actual or suspected soiling has occurred will probably reduce the incidence of peritonitis and death.

It produces high local concentrations within the peritoneal cavity—from seventy-five to one hundred times the level reached in the circulating blood. This high local concentration seems to have a bacteriostatic or destructive effect on the bacteria.

There have been no serious local or general toxic effects of the drug when used in the recommended doses. The dose advised is 175 mg. of sulfanilamide per kilogram of body weight, two thirds to be applied intraperitoneally and one third in the wound layers. The total dose should never exceed 18 Gm., and this amount should be used only in cases of unusually severe involvement.

There have been no deaths among 268 patients with acute appendicitis since its use was commenced in January 1940. This experience encourages us to endorse whole heartedly the use of sulfanilamide intra-

* Many of these cases came to autopsy and in each case peritonitis was not found. A few patients died several hours postoperatively from shock due to the grave injuries. A few died two to three weeks postoperatively. The remainder died of pneumonia or of cardiorenal failure. Five patients with diverticulitis and peritonitis were operated on without a death.

† (P) prophylactic; (T) therapeutic.

peritoneally when indicated. We do not wish to give the impression that the mortality rate in cases of acute appendicitis will henceforth approximate zero, as we feel unusually fortunate that there were no deaths from embolism or other conditions entirely dissociated from peritonitis. We are firmly convinced that the application of this new weapon will lower mortality rates in all forms of peritoneal infection.

NOTE—Since this article was read in Cleveland the completed statistics on the intraperitoneal use of sulfanilamide as of Jan. 5, 1942 show that operations in 400 cases of acute appendicitis have been performed at the Roosevelt Hospital without mortality. About one third of these, 133 cases, were severe enough for the use of intraperitoneal sulfanilamide.

Instead of estimating the amount of sulfanilamide to be used by milligrams per kilogram of body weight, an easier guide for dosage is to take 8 per cent of the pounds of body weight in order to obtain the number of grams of sulfanilamide to be used in the average case in which drainage is employed. In the average case without drainage 6 per cent of the body weight in grams gives the proper amount, allowance always being made for the degree of infection present; i. e., more or less being used than the amount estimated according to the degree of infection present.

FREDERICK A. COLLER, M.D.

ANN ARBOR, MICH.

Implantation of crystalline sulfanilamide in the peritoneal cavity has been practiced by many surgeons during the past year. Local application of sulfanilamide and its derivatives has been a valuable method of utilizing these drugs. In 1939 Jensen, Johnsrud and Nelson¹ reported the implantation of sulfanilamide in compound fractures with a considerable reduction in the usual incidence of infection. Burns, chronic ulcers, infected wounds, mastoid cavities, the lesions of acute and chronic osteomyelitis, meningeal abscesses and infected pleural cavities all have been treated with topical chemotherapy.

When sulfanilamide first came into use it was felt to be effective primarily against infections with hemolytic streptococci. With sulfanilamide treatment, a reduction in mortality due to primary streptococcal peritonitis was reported.² In peritonitis associated with appendicitis the infection is often a mixed one, with colon bacilli, Welch bacilli and various strains of streptococci commonly participating;³ yet Ravdin, Rhoads and Lockwood⁴ found such peritonitis favorably influenced by sulfanilamide therapy. At about the same time Garlock and Seley⁵ reported the successful use of sulfanilamide in preparation for operations on the colon.

It is not surprising, therefore, that the local use of sulfanilamide in the peritoneum was tried. Rippey⁶ has used sulfanilamide intraperitoneally in treating gunshot wounds of the abdomen. Within the past year Dees,⁷ Rosenberg and Wall⁸ and Thompson, Brabson and Walker⁹ have advocated the local application of sulfanilamide in the treatment of acute appendicitis. Wangenstein¹⁰ reported the intraperitoneal use of powdered sulfanilamide in resections of the colon.

There is a sound rationale for the local use of sulfanilamide for both the treatment and the prophylaxis

of peritoneal infection. Lockwood and Rhoads¹¹ have emphasized that an inflammation of a serous surface is the type of lesion which might be expected to respond favorably to chemotherapy. The organisms most commonly found in peritonitis are susceptible to the drug.¹² In the usual concentrations and in the tissues sulfanilamide and its derivatives are probably only bacteriostatic.¹³ If these drugs are accepted as bacteriostatic agents, infection or contamination of the peritoneum is a likely situation in which to employ them. By halting bacterial multiplication the drugs place the bacteria more completely at the mercy of the capable natural defenses of the peritoneum.

In general the effectiveness of sulfanilamide is proportional to its concentration. There are modifying factors, such as the nature of the lesion and the character of the exudate, for the wall of an abscess may form a barrier beyond which the blood-borne drug passes with difficulty, and an exudate rich in the products of tissue necrosis contains inhibiting substances.¹⁴ The local use of sulfanilamide is advantageous, because the drug can be placed in the center of a suppurating or contaminated area, where its local concentration becomes maximal. In the absence of suppuration even more favorable results can be expected, because no inhibiting substances are

Chart 1.—Curve for absorption of sulfanilamide in dog 848 (weight 10 Kg.) following intraperitoneal implantation. Two Gm. of sulfanilamide, or 0.2 Gm. per kilogram, was given.

present. Under these circumstances the use of sulfanilamide in the peritoneum is similar to its local use in compound fractures, where contamination exists but frank suppuration is not established. Therefore, when open anastomoses have been made, when there has been accidental soiling of the peritoneum with the contents of the gastrointestinal tract, when walled-off abscesses have been broken into and the remainder of the abdomen exposed to contamination, then local chemotherapy should be of great value in aiding the natural peritoneal defenses.

During the past eighteen months we have used sulfanilamide intraperitoneally in suitable patients. We were uncertain what were safe doses and what harmful effects might result. Lockwood and his co-workers¹⁵

have pointed out that there are hazards in using large amounts of sulfanilamide locally, for once the drug has been given its rate of absorption cannot be controlled and accidents may occur in sensitive patients.

Studies of the absorption of sulfanilamide by the peritoneum were carried out both on patients and on

Chart 2.—Curve for absorption of sulfanilamide in dog 846 (weight 10 Kg.) following intraperitoneal implantation. Four Gm. of the drug, or 0.4 Gm. per kilogram, was given.

dogs. These studies were done on relatively normal peritoneal surfaces, and our figures may differ from those of investigators who have worked in the presence of peritonitis. Known amounts of sulfanilamide were placed in the peritoneal cavity and determinations of the sulfanilamide in the blood made at given intervals. Curves were drawn plotting the blood concentration against time. Absorption of the drug by the peritoneum is rapid. The amounts in the blood rise to high levels during the first two or three hours and fall off gradually to low levels at the end of twenty-four hours.

In dogs large doses per kilogram of body weight were employed. It seems that there may be a limit to the rate at which the peritoneum can absorb the drug, since the larger the dose the longer the interval before the peak is reached. Yet repeated experiments with doses up to 0.5 Gm. per kilogram (the equivalent of nearly 35 Gm. for a 150 pound [68 Kg.] man) showed the peak to be reached before four hours. Very high levels were reached in the dogs, the values going as high as 40 mg. per hundred cubic centimeters of blood. When these high levels were attained there were still significant amounts in the blood at the end

Chart 3.—Curve for absorption of sulfanilamide in dog 847 (weight 13 Kg.) following intraperitoneal implantation. Six Gm., or 0.46 Gm. per kilogram, was given.

of twenty-four hours, but at forty-eight hours the drug had nearly disappeared (charts 1, 2 and 3).

To compare absorption from the intestine with that from the peritoneum, fasting dogs were given the same amount of sulfanilamide by stomach tube as had been

given others of similar weight by peritoneum. When the drug was given into the peritoneum the peak was reached in three hours. When it was given into the stomach the level in the blood was still rising at twenty-four hours (chart 4).

In an attempt to slow the absorption of the drug and maintain a high local concentration for a longer time, sulfanilamide was suspended in a tragacanth-aleuronat mixture similar to that used in preparing Steinberg's coli-bactragen¹⁶ and injected into the dog's peritoneum. There was no appreciable slowing of the absorption (chart 5).

In human subjects doses greater than 5 Gm. of sulfanilamide were seldom used. Peak levels of nearly 10 mg. per hundred cubic centimeters were usually reached in about two hours, and at twenty-four hours levels below 2 mg. were found. There was considerable variation among individual subjects, for high levels of 16 to 18 mg. were observed in a few patients and relatively low ones in others (charts 6 and 7).

We have studied the records of 62 patients who have received sulfanilamide intraperitoneally during the past eighteen months at the University Hospital. There were three general indications for intraperitoneal admin-

Chart 4.—Absorption of sulfanilamide in dog 847 (weight 13 Kg.; dose, 6 Gm. of powdered sulfanilamide given intraperitoneally) and in dog 937 (weight 12 Kg.; dose, 6 Gm. of the powdered drug given by stomach tube). The dotted line indicates the absorption of sulfanilamide from the peritoneum and the solid line the absorption from the intestine.

istration: operations in which spreading peritonitis was encountered or areas of intraperitoneal suppuration were entered; operations involving resection or anastomosis of the colon; operations on the upper portion of the gastrointestinal tract in which because of technical problems it was felt that the peritoneum had been soiled by intestinal contents. Several patients had stage operations, and the drug was used in them more than once, so that in the 62 patients sulfanilamide was implanted sixty-seven times (table 1).

The 62 patients can also be grouped on the basis of whether supplemental sulfanilamide medication was given. Thirty-three patients received no other chemotherapy, whereas 29 were given other sulfanilamide medication. All of the latter received sulfanilamide intravenously for at least one day postoperatively, and some received it orally later. Seven were prepared for operation by sulfanilamide medication (table 2).

In the 62 patients, whose chances of incurring peritonitis or of growing worse from established peritonitis were considered likely, only 5 had evidence of post-operative intraperitoneal suppuration. Two of the 5 were among the patients who received supplemental sulfanilamide. Of these 2, 1 with peritonitis compli-

16. Steinberg, Bernhard: Coli-Bactragen in Prevention of Peritonitis. *Am. J. Clin. Path.* 6: 253 (May) 1936.

cating appendicitis had a pelvic abscess but recovered after drainage and the other died of peritonitis when an open suture line at the site of an anastomosis between the stomach and the esophagus allowed continual peritoneal soiling attended with chemical necrosis. A third patient had peritonitis secondary to a wound infection

appearing several days after sulfanilamide treatment had been stopped. The other 2 had gastric resections and received sulfanilamide only at operation. One recovered after drainage of a subphrenic abscess on the left side, and the other died, twenty-eight days after gastric resection, of a condition reported by the pathologist as low grade peritonitis. While this small series is uncontrolled, we feel that the use of sulfanilamide reduced the incidence of complications and failure which might have been expected and that the unfavorable results in 3 cases might have been averted by prolonged sulfanilamide treatment. Sulfanilamide medication is often attended by toxic reactions.¹⁷ In our series none of the patients receiving only the intraperitoneal dose of the drug showed any toxic signs. Among the others there were frequent instances of cyanosis. Nausea could not be evaluated because of the type of patient. No cases of drug fever could be singled out. Granulocytopenia did not occur, and there were no drug rashes. But among the 29 patients who received additional sulfanilamide therapy one complication stood out glaringly, the development of jaundice in 9. It was definitely felt that the jaundice was due to hepatic damage in all instances, for there was no hemoclasia or sepsis to account for it otherwise.

Fortunately the development of icterus had no immediate untoward consequences. Except on one occasion

Chart 5—Curve for absorption of sulfanilamide in dog 933 (weight 11 Kg.) following intraperitoneal implantation of 4 Gm of the powdered drug suspended in a tragacanth aleuronat mixture.

administration of the drug was stopped as soon as jaundice was noticed, and the jaundice rapidly cleared. The bilirubin level, determined by the van den Bergh method, varied from 2.5 to 20 mg. per hundred cubic

centimeters, as compared with a normal of 0.1 mg. The reactions were direct, indicating a regurgitation type of jaundice. A patient who died a month and a half after operation of residual carcinoma and who had had jaundice which cleared showed no evidence of residual hepatic damage at autopsy. Data on the patient who became most deeply jaundiced are shown in chart 8. In her case because of extensive fecal soiling at operation the threat of peritonitis was considered so great that sulfanilamide medication was continued even after the jaundice had developed. The blood bilirubin level increased for several days after sulfanilamide therapy was stopped, but the jaundice eventually disappeared. Her postoperative course was otherwise gratifying, and after several months she showed no evidence of residual hepatitis.

Of the 9 patients in whom hepatitis developed none received more than 5 Gm. of sulfanilamide intraperitoneally, but 6 received additional sulfanilamide on the day of operation. The interval between operation and the appearance of jaundice varied from twenty-four hours to seven days (table 3).

Hepatitis has often been observed during sulfanilamide therapy.¹⁸ Long and his associates¹⁷ reported a 0.6 per cent incidence of jaundice in a series of 1,000

Chart 6—Curve for absorption of sulfanilamide in W. S. (weight 120 pounds [54.4 Kg.]), who underwent partial colectomy for ulcerative colitis on Feb. 28, 1940. Four Gm of sulfanilamide suspended in saline solution was placed in the peritoneal cavity.

patients. Watson and Spink¹⁹ observed hepatitis in 16 of 110 patients, an incidence of 14.6 per cent. These authors included 2 fatal cases of jaundice which followed intraperitoneal implantation of the drug. In those cases the doses used were 10 and 12 Gm., respectively. The high incidence of jaundice in our small group seemed important to us. In analyzing the cases it appeared that jaundice was more common in the patients who received the most intensive therapy and probably had the highest levels of drug in the blood. The question arose whether the intraperitoneal application of the drug might be more apt to lead to hepatitis than administration by other routes.

Dogs were given sulfanilamide intraperitoneally, and at various intervals the portal vein was exposed and blood specimens were withdrawn simultaneously from it and from the jugular vein. Attempts to cannulate the portal vein and obtain serial specimens were unsatisfactory, and so a series of isolated experiments was

done. The fact that a large number of experiments was not carried out probably detracts from the accuracy of our figures. These studies revealed that during the absorptive phase the concentration of sulfanilamide was considerably higher in blood from the portal vein than in the peripheral blood. Thirty minutes after the

Chart 7.—Curve for absorption of sulfanilamide in H. P. (weight 142 pounds [64.4 Kg.]), who underwent ileotransverse colostomy for carcinoma of the cecum on April 22, 1940 and was prepared for operation by the oral administration of sulfanilamide for three days. At the time of intra-peritoneal implantation (5 Gm. was given) there was a level of sulfanilamide in the blood of 7.3 mg. per hundred cubic centimeters.

administration of the drug the difference between the sulfanilamide content of the portal vein blood and that of the peripheral blood was approximately 40 per cent of the peripheral blood level (chart 9). At the end of four hours the concentrations were the same.

This initial high concentration of sulfanilamide in blood from the portal vein when the drug is absorbed by the peritoneum may cause more insult to the liver than is caused when the drug is absorbed more slowly. Greene and Hotz²⁰ reported on a patient with hepatitis following sulfanilamide medication who died and was autopsied. Tissue assays were made, and it was found that a concentration of 6 mg. per hundred grams was present in the liver, as compared with a concentration

Chart 8.—Levels of bilirubin and of sulfanilamide in the blood in I. S. Deep jaundice developed in this patient twenty-four hours after administration of sulfanilamide. She was prepared for operation, which is represented in the lower part of the chart, on February 27. I. P., intraperitoneal medication.

of 1 mg. per hundred grams in the lungs. These authors suggested that there is perhaps a special affinity of the liver for the drug. If this is so, the passage of

high concentrations in the portal vein during the early stages of absorption may allow the liver to saturate itself with more sulfanilamide than it can safely handle in the face of subsequent medication. In our investigations no tissue assays were made. Sections of liver from dogs who received the drug intraperitoneally were examined microscopically and failed to show significant or specific changes which could be attributed to sulfanilamide.

Another interesting phase of the intraperitoneal implantation technic is the local mechanical effect of the sulfanilamide. During the period of absorption from the dog's peritoneum samples of peritoneal fluid were aspirated through capillary pipets and examined microscopically. There was no cellular response. Up to two hours later sulfanilamide crystals were found in the fluid, but none were found thereafter. Animals which had been given sulfanilamide intraperitoneally were killed from four hours to one month later and their abdominal cavities examined. In those killed after four hours small amounts of fluid were observed but there was no hyperemia and no exudate or crystals. In those killed later the peritoneal surfaces appeared entirely normal. No adhesions were formed. On microscopic examination of the serosal surfaces no variation from normal could be detected.

Chart 9.—Level of sulfanilamide in the blood of dog 942 (weight 12 Kg.). The small circle charted at one-half hour represents the value for sulfanilamide in portal vein blood; the other points on the chart indicate values for jugular vein blood.

On the other hand, there is some reason to believe that sulfanilamide therapy may do much to prevent peritoneal scarring. Two patients treated intraperitoneally with sulfanilamide for diffuse purulent peritonitis died of other causes and have subsequently been seen at autopsy. In each instance it seemed remarkable that the angry process seen at operation had subsided without more adhesion formation. In each case the only gross evidence of the previous peritonitis was a single fine adhesive band. It is likely that chemotherapy alters the peritoneal reaction in infection. We have seen abscesses rendered sterile by sulfanilamide and its derivatives. Recently we treated a patient with staphylococcal septicemia and acute osteomyelitis, using sulfathiazole. The patient later had pericarditis with an effusion from which staphylococci were obtained by smear and culture. Yet typical purulent pericarditis never developed, for the effusion never contained more than 3,000 white blood cells per cubic millimeter. Eventually the effusion disappeared and the blood culture became sterile. It remains to be seen whether any permanent pericardial changes have occurred, but it is reasonable to suppose that there will be less scarring than there would be if the exudate had contained much fibrin and large numbers of pus cells. In the same way sulfanilamide may modify the process of inflam-

²⁰ Greene, C. H., and Hotz, R. Liver and Biliary Tract. Review for 1938, Arch. Int. Med. 63:779 (April) 1939.

mation in the peritoneum and, in addition to allowing recovery of the patients by controlling the infection, reduce the incidence of scarring with the formation of adhesions during the healing phase.

Another series of experiments was carried out in an attempt to evaluate sulfanilamide therapy in experimental peritonitis. Fecal peritonitis was induced in one group of 24 dogs. A fecal suspension was prepared by taking a weighed amount of fresh cage feces, suspending it in saline solution and filtering it through gauze. This was injected into the peritoneal cavity through a trocar. Experiments were all carried out on dogs in pairs, one dog being protected with sulfanilamide and the other being used as a control. The dogs were inoculated with equal doses varying from 1.5 to 5 Gm. of feces suspended in 50 cc. of saline solution. Four Gm. of sulfanilamide powder suspended in 100 cc. of saline solution was injected into the peritoneal cavities of the protected dogs and 100 cc. of plain saline solution into the cavities of the controls. It was not possible, in working in this fashion, to standardize the fecal inoculum, the dose being more virulent on some occasions than it was on others.

There were twelve paired experiments. In 4 the protected dog survived and the control died. In 1 both animals survived. In the 7 other experiments both

Chart 10.—Difference between the levels of sulfanilamide in portal vein blood and those in jugular vein blood, the sulfanilamide having been given intraperitoneally. The points on the chart were obtained by averaging the results of various experiments and represent the percentage of difference between the levels of the drug in specimens from the two sources withdrawn simultaneously at various intervals.

animals died, but the average survival time of the protected animals was twenty hours while that of the controls was twelve hours. This cannot be accepted as anything but suggestive evidence of the value of sulfanilamide treatment.

In an effort better to control the degree of infection, colon bacillus peritonitis was induced in another group of animals. The method of Steinberg and Goldblatt²¹ was used, various amounts of agar cultures of *Escherichia coli* (colon bacillus 300—Steinberg) being suspended in a tragacanth-aleuronat mixture. Thirty animals were employed in groups of 6, 3 in each group being protected with sulfanilamide, as in the group with fecal peritonitis, and the other 3 being used as controls. Doses of *Esch. coli* ranged from one half to one twenty-fifth of a twenty-four hour slant. Actually more control animals than treated animals survived. Possibly the use of the tragacanth-aleuronat mixture interfered with the usual action of sulfanilamide. Tragacanth is supposed to prevent by some mechanical action the rapid transport of the colon bacilli into the blood stream. This may interfere with the action of the drug either mechanically or because of some inhibitor substance.

Various conclusions may be drawn from these observations. In the first place, we feel that results were

gratifying in our group of patients who were treated intraperitoneally with sulfanilamide either to prevent or to overcome peritoneal infection.

Absorption of sulfanilamide from the peritoneum free of suppuration is rapid. It may be slower from the cavity of an appendical abscess, and there is every reason to suppose it would be. In the relatively normal

TABLE 2.—Incidence of Jaundice

abdomen the absorption is so rapid it is doubtful that the local use of sulfanilamide in the peritoneum is analogous to its local use in parts of the body where absorption is slower. It would be ideal if some method could be devised which would prevent the rapid absorption of the drug and allow it to remain in a higher local concentration. Perhaps more reasonable would be use of some allied compound with the same action which would be absorbed less readily and remain effective in the local sense longer.

Countering the rapidity of absorption from the peritoneal cavity is the fact that peritoneal administration offers the fastest method we know to raise the concentration in the blood to effective levels. If a spreading peritonitis is found at operation or if, because of technical difficulties, unforeseen contamination occurs, it is desirable to get effective chemotherapy started as soon as possible. If not overdone, intraperitoneal implantation is a fairly safe and extremely rapid method of administering sulfanilamide.

In the group of patients reported here there was a high incidence of hepatic damage. During the rapid absorption from the peritoneum the concentration of sulfanilamide in the portal vein blood reaches higher

* These 9 patients all received supplemental medication

levels than are reached when the drug is administered by other routes, and this may increase the danger of hepatitis. At least this incidence of jaundice emphasizes a hazard of intraperitoneal chemotherapy with too large amounts of the drug. In retrospect it seems that several of our patients in whom jaundice developed were given too much sulfanilamide on the day of operation. After an intraperitoneal dose of 5 Gm. of sulf-

21. Steinberg, B., and Goldblatt, H.: Studies on Peritonitis: Passage of Bacteria from the Peritoneal Cavity into the Lymph and Blood, *Arch. Int. Med.* 39: 449 (March) 1927.

anilamide an interval of eighteen hours or more should elapse before further medication. In face of active infection it would seem wise to continue sulfanilamide treatment to obtain optimum results. When sulfanilamide is used prophylactically additional medication should depend on the clinical estimate of the degree of contamination and the power of the patient to resist it. Fortunately, no deaths due to hepatitis occurred in our series, and likely this is because larger doses were not used. From our experience we would be loath to use amounts of sulfanilamide much greater than 5 Gm. in the peritoneal cavity.

SUMMARY

1. The local implantation of sulfanilamide is of value in treating peritonitis and in aiding the peritoneum to overcome contamination occurring at operation.

2. Sulfanilamide is absorbed so rapidly from the peritoneal cavity that it is uncertain whether it is effective as a local medication in the same sense that it is in other parts of the body.

3. The peritoneal route offers the fastest method of administering the drug so that effective levels in the blood are reached.

4. There was a high incidence of hepatitis in the patients in this series, and the administration of doses larger than 5 Gm. is advised against.

5. There is no evidence that the local application of sulfanilamide injures the peritoneal surfaces, and it is suggested that chemotherapy offers promise of reducing scarring (adhesion formation) in the peritoneum secondary to pyogenic infection.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRs. MUELLER AND THOMPSON
AND DRs. JACKSON AND COLLIER

DR. HENRY W. CAVE, New York: We have had at the Roosevelt Hospital a large experience with acute appendicitis. There were 742 patients suffering from this disease from 1935 to 1939, and in the past fifteen months there were 268 patients, 90 of whom were treated with sulfanilamide intraperitoneally without a single death. In only 1 instance in the entire series of 90 cases was there jaundice. The approximate dose was 12 Gm. per patient or 170 mg. per kilogram of body weight, and the sulfanilamide powder was placed in sterile test tubes, usually 2, 4, 6 and 8 gram doses, and sterilized by dry heat for two hours at 140 C. The peak of the blood level is reached in ten to eighteen hours. Generally, after two hundred hours no trace of sulfanilamide is found in the blood. There have been noted no toxic manifestations from intraperitoneal sulfanilamide in this series of over 200 patients. Also there has been no evidence of liver damage. The blood concentration is not important in peritoneal infections, but we are convinced that high local peritoneal concentration is important and is an active factor in controlling the disease. I am not convinced that peritoneal concentration is as of short duration as Drs. Jackson and Collier stated. We have demonstrated a peritoneal concentration as high as 600 mg. as long as thirty-six hours after operation. In other words, rapid fall in the blood level postoperatively is not paralleled by the fall in the peritoneal level. We have encountered, even three days postoperatively, sulfanilamide crystals in the peritoneal exudate. The 90 patients were all critically ill. All of these patients were immediately operated on. It is interesting that in Drs. Jackson and Collier's series the only patients acquiring jaundice were those who had daily received intravenously large doses of sulfanilamide in addition to the original peritoneal dose. I believe that if a sufficiently large intraperitoneal dose is used at operation it is not necessary

to give sulfanilamide compounds by rectum, by mouth or intravenously. Thus, toxic symptoms are unlikely to occur. It has been stated in both of these papers that sulfanilamide has been used in peritoneal infections other than acute suppurative appendicitis and as a preventive of infection within the peritoneum in all forms of resections of the intestine, end to end, side to side, end to side anastomoses, after hysterectomy and other abdominal operations. It has been my own practice to place around anastomoses inside the abdomen 4 to 6 Gm. of sulfanilamide crystals for their bacteriostatic effect. In some 5 cases of ulcerative colitis in which a subtotal colectomy was done we placed sulfanilamide in the peritoneal cavity; even in spite of this there were two deaths from peritonitis in this series of 5 in which we had used the drug.

DR. JAMES E. THOMPSON, New York: Dr. Mueller has shown a dramatic reduction in mortality from acute appendicitis following the introduction of sulfanilamide as an adjunct in the treatment of acute appendicitis with perforation. The effect of sulfanilamide is emphasized also by a reduction in such complications as secondary peritoneal abscesses; wound complications also were less, and we found that prolonged wound drainage was less. We have used sulfanilamide in a total of 90 cases as a prophylactic measure in surgery of the large intestine when there has been gross or suspected contamination, and in these we have had eight deaths. We have also used it as a therapeutic measure in 21 cases in which we have encountered peritonitis from causes other than acute appendicitis and have had six deaths, a rather staggering mortality rate; but these were unusually serious cases. The blood levels were taken in all our original cases, but only recently did we begin to get peritoneal levels in a few of our serious cases of appendicitis with peritonitis. A test tube is attached to one of the drains (if it was drained with two drains), a clamp put on the other one, and the collected fluid drained off from it. In 1 case at the end of seventeen hours the fluid was analyzed and found to contain 200 mg. of sulfanilamide per hundred cubic centimeters. In 1 case of perforated appendicitis with peritonitis, at the end of three hours we got a level as high as 880 mg. per hundred cubic centimeters, which dropped down at the end of five hours to around 200. In a case of acute appendicitis with abscess formation, in which we have placed 6 Gm. of sulfanilamide into an abscessed cavity around the cecum, 12 Gm. was placed in it. The abdominal wall was closed snugly about the drain. There was a prompt rise at the end of three hours to around 400 mg. per hundred cubic centimeters. It then reached the peak, which was around 780 mg. and dropped down again, going up at the end of thirty-six hours to 660 mg. Our culture at operation was a pure culture of *Bacillus lactis aerogenes*, while a culture at the end of thirty-six hours showed *B. lactis aerogenes* and the gamma streptococcus. The appearance of the streptococcus in a secondary culture has been rather frequent in our experience. Two features are evident: (1) that one can get a fairly well maintained local level of sulfanilamide for a period as long as thirty-six hours postoperatively and (2) that the sulfanilamide does not act as a true bactericidal agent but probably as a bacteriostatic one.

DR. ALTON OCHSNER, New Orleans: Our results have not been as dramatic as Drs. Mueller and Thompson's. We have observed some cases of jaundice and have seen some bad results from the implantation of sulfanilamide in the abdominal wall because of the exudation which is set up. Undoubtedly, many of these wounds can and will heal better with sulfanilamide than if allowed to become infected; still I think it should be emphasized that, unless there is gross contamination, sulfanilamide should not be used. Sulfanilamide produces an intense reaction of the wound, excessive exudation of serum and a prolonged healing. I should like to call attention to the advisability of not draining the peritoneal cavity in cases of generalized peritoneal infection or contamination. Dr. John Yates demonstrated experimentally almost forty years ago that it is impossible to drain the peritoneal cavity for so long as four to six hours, because after this time the drains become walled off and drainage is only along the course of the drain. A

number of years ago while serving as an exchange assistant in the Zurich Surgical Clinic I had an opportunity to compare the results obtained in cases in which the peritoneal cavity was drained with those obtained in cases of peritonitis in which no drainage was used. During the time Professor Sauerbruch was director of the clinic drainage was done in all cases, whereas during Professor Clairmont's tenure drainage was not done in the presence of generalized peritonitis. It is of significance that the incidence of residual abscess formation was considerably higher in the cases in which drainage was used prophylactically. This is undoubtedly due to the fact that the drain as a foreign body increases the peritoneal reaction and tends to produce pocketing. I think that, if one is to use sulfanilamide, drainage should not be used in the peritoneal cavity. I was interested in Dr. Mueller's statement that they were using sulfathiazole in conjunction with sulfanilamide. A word of warning about the use of sulfathiazole in serous cavities. I know of 2 cases with optic lesions, 1 a permanent optic atrophy, which resulted from sulfathiazole administration in sepsis and another a temporary optic lesion following sulfathiazole implantation in the pleural cavity. Whether this is a coincidental finding and what the connection is I don't know, but we have learned to fear sulfathiazole given intraserosally, probably because of the rapid absorption. Would it not be better to use possibly not as large a dose as Drs. Mueller and Thompson used, namely 12 Gm., but a smaller dose, as Drs. Jackson and Collier suggested, and repeat that in another four to five hours?

DR. FREDERICK A. COLLIER, Ann Arbor, Mich.: We have heard two presentations dealing with the curative aspects of sulfanilamide, the other, Dr. Jackson's, discussing largely the preventive aspects. We do know from past work that if there is an exudate in the peritoneum there will be a sharp limitation of absorption, and the facts presented by Drs. Mueller and Thompson bear that out very well. Those facts have been proved before. One cannot gainsay the evidence as presented by Dr. Jackson that in the normal peritoneum, whether in the experimental animal or whether one is using it in the comparatively normal peritoneum that has been contaminated, the absorption is more rapid and lasts for a very much shorter time. We have examined microscopically and grossly the peritoneum of many animals that have had enormous amounts of sulfanilamide placed there both in solution and as a powder, and we have yet to find any evidence of harm that has accrued to the peritoneum from the presence of even enormous amounts of the powder itself. The drug is not a panacea. I am sure, in operating on patients with peritonitis and acute appendicitis and with abscess that the proper time for operation was chosen, due thought was given to the type of anesthetic, and the chemical abnormalities of the patient were carefully corrected. We must emphasize the fact that chemotherapy is an adjunct to good surgery and will not replace it. I find that many physicians are now using these various drugs in all clean operations. Some one asked me the other day why it would not be a good idea to sprinkle it in the wound after a radical mastectomy. Those wounds do well if they are done with the good surgery that we already know about. I think it unwise to use these chemicals in the hope that they will improve what otherwise might be called inadequate surgery. There is one point that I should like to mention in closing (Dr. Ochsner has already mentioned it), and that is our use of these chemicals in the contaminated abdominal wall. Many times, let us say, we operate on a colon, the clamp slips, and we deal with a contaminated peritoneum. Certainly we shall use sulfanilamide there and shall expect some help from it. On the other hand, if the virgin abdominal wall that has never been in contact with infection of any kind until the incision is made is contaminated with the contents of the colon, it has been suggested that these chemicals be used in the wall. My experience is just exactly that mentioned by Dr. Ochsner, that it makes a messy wound, no matter how one uses it. These salts are hygroscopic, and they have a peculiar glazing or coagulating action on the fat of the subcutaneous tissue which I do not like.

DR. F. L. REICHERT, San Francisco: The use of chemotherapy in the peritoneal cavity brings up the question as to what happens when a powder is placed in it. The interesting fact that was brought out in the discussion as well as in Drs. Jackson and Collier's paper was that they experimentally, in normal animals, found that there was no reaction whatever to the use of sulfanilamide. Dr. Laird and Dr. Stavern, in the surgical research laboratory at Stanford, have placed the powder of sulfanilamide and of sulfathiazole intraperitoneally into normal dogs and have found in general that there has been no reaction in the peritoneum or in the omentum but that there has been some reaction in the wound of the abdominal wall. When sulfathiazole was used, about 0.5 mg. per kilogram, there was some induration of the root of the mesentery. There were no adhesions, but in the abdominal wound there was considerable secretion. They also used sodium sulfathiazole and found severe reaction, with adhesions and matting together of the loops of bowel and mesentery. Sodium sulfathiazole has a pH of about 11, whereas sulfanilamide and sulfathiazole have a neutral pH of about 6.3 or 6.5. From their experimental work I think one is justified in using sulfanilamide and sulfathiazole powder intraperitoneally; certainly not sodium sulfathiazole.

DR. MISCH CASPER, Louisville, Ky.: I have used sulfonamide agents in many cases of ruptured appendix and acute peritonitis. I used it once in a perforated stomach that was seen after twenty-four hours' delay, the perforation being due to a stab wound, one perforation on the anterior wall of the stomach and two in the lesser sac. The peritonitis was limited to an area about 8 or 10 inches in diameter, and sulfathiazole was used in this case without any bad results. It looked like a good case in which to try it, because there was developing already a definite area of peritonitis, which may have been a chemical form of peritonitis. Also sulfathiazole was used in 1 case of cesarean section. It had been a badly handled case before it came to the hospital. It had been examined and reexamined by no fewer than five doctors. We contented ourselves with placing sulfathiazole into the emptied uterus, also on the peritoneal line of stitches on the uterus and in the wall. I do not remember any similar case reported before. The patient came through without any elevation of temperature and with a normal recovery. We have lately been using sulfathiazole instead of sulfanilamide. We used only 7 Gm.; that is the highest amount we have used in the abdomen, and 2 in the wall. I feel sure that in these sulfonamide drugs we have one of the greatest agents for cure in all time, ranking certainly with the ten most useful drugs. We have had no cases of jaundice following this procedure. That may be because we use a smaller dose than some of the others. I should like to call attention to an old professor's saying that anything that is potent for good is also potent for evil; hence, no doubt cases in which the sulfonamides are used rather indiscriminately will show up some evils in the future, and we must watch out for those.

DR. R. STERLING MUELLER, New York: In our series of cases from Roosevelt Hospital we have used it in only the severe cases. We would not use it in a clean or only slightly contaminated case. But if one is going to use it in the abdominal wall in an undrained case in which there is slight contamination, one must be sure to spread the drug around, to deposit it around the wound so that it does not form a mass in one spot, because those cases especially will show a reaction. I also want to warn against using sulfanilamide intraperitoneally in those cases in which sulfanilamide compounds have been used preoperatively. We feel that the advantage of the larger dose makes it unnecessary to give it postoperatively. In the last few months there have been but few cases in which we have given it after operation. I think that if one does give it in cases in which it was used preoperatively, and especially in those cases in which it is used postoperatively by the intravenous route, one might see jaundice. In reply to Dr. Ochsner's suggestion about giving it at two different times four or five hours apart, I do not believe that would help any. We prefer giving the larger dose. We believe that the fibrin which masses around the crystals prolongs its absorption.

CESAREAN SECTION

INDICATIONS FOR AND RELATIVE MERITS
OF THE CLASSIC, LOW AND EXTRA-
PERITONEAL OPERATIONS

S. A. COSGROVE, M.D.

AND

J. F. NORTON, M.D.

JERSEY CITY, N. J.

The indications recognized as valid in modern practice for the exhibition of cesarean section are numerous. Historically, this operation has been employed only for high degrees of fetopelvic disproportion. Indeed, until about fifty years ago its validity on any other grounds was not recognized. Up to that time it was so dangerous as to be applicable only to what was known as the absolute degree of pelvic contracture, because of which not even a mutilated dead baby could be otherwise removed from its mother's body, and the relative degree of contracture, which meant that a living baby could scarcely be otherwise delivered.

In the last forty to fifty years, however, the term relative disproportion has become so liberalized as to connote any degree of fetopelvic disproportion which makes vaginal delivery unusually difficult or carries more than a minimum hazard for the baby's survival in vaginal delivery. This trend, while undoubtedly conservative in expert hands, has been pernicious in the hands of the occasional operator lacking the obstetric capacity adequately to judge corollary conditions affecting individual situations.

Paralleling the more liberal attitude involving the fetopelvic relation of size is the use of cesarean section for other mechanical interferences with labor, such as malpresentation, occasional factors of dystocia of the soft parts of the birth tract and tumors extrinsic to the uterus.

Another group of indications comprises nonmechanical abnormalities peculiar to the pregnant state, such as certain types of placenta previa, abruptio placentae and severe, rapidly progressive toxemia.

Still another group involves disease conditions in the mother not primarily dependent on the pregnancy, such as tumor of the uterus or other organs not necessarily mechanically obstructing labor but indicating from its nature operative ablation, rare cases of heart disease, diseases of the central nervous system and acute infectious diseases.

All the foregoing groups of indications are today generally accepted as valid provided that treatment in individual cases is determined with average good obstetric judgment. There are many other indications, however, for which cesarean section has been not infrequently used, such as primigravidity in the elderly, election by neurotic patients and high social value of the offspring, which can hardly be considered legitimate unless assessed with an extraordinary degree of conscientious thought and obstetric competence in individual cases.

With reference to what has so far been said, therefore, cesarean section should ordinarily not be undertaken at all except with the concurrence of at least two physicians, one of whom should be, if possible, an

obstetrician of acknowledged competence and experience. This rule should govern its employment according to definite regulations in all properly organized hospitals.

A brief tracing of the history of the operation indicates that up to the period of anesthesia and antisepsis the technic was exceedingly crude and not designed to cope successfully with the hazards of hemorrhage and infection. It was only when antisepsis and asepsis were applied to surgery and Sanger pointed the way toward adequate control of hemorrhage by careful suture of the uterine incision that the expansion of the availability of the operation as already sketched was possible. Sanger's operation, which involved a high paraumbilical incision of the parietes and a uterine incision placed longitudinally about in the midline of the corporeal segment of the uterus, well up toward the fundus, has become known as the classic type of cesarean section. Great as was the improvement of this technic on the older ones, however, it has several serious inadequacies. Spill of uterine contents and blood into the peritoneal cavity cannot be avoided, even by the most careful packing about the uterine incision; moreover, this spill involves the upper, less resistant portion of the peritoneum. The incision in the uterus involves the thickest and generally most vascular portion thereof. Hemorrhage is apt to be relatively profuse and accurate coaptation by sutures difficult. As a result, healing by

TABLE 1.—Classic Section, Sixty-Eight Cases

first intention is frequently imperfect and a weak scar remains in the portion of the uterus which is called on to do the most work in a subsequent delivery. Hence the incidence of rupture of the scar, both in our own experience and in experience reflected in many published series, has been high. The dangers inherent in rupture have therefore to be assessed against the indications for the original operation in cases in which it occurs.

In earlier experience of cesarean section, the tendency to employ it as a late necessitous procedure on patients already infected by prolonged labor and mishandling led to a high death rate from peritonitis. Numerous attempts were therefore made to devise technics that would lessen the risk. The first important contribution to the evolution of operative technic was the operation of Porro. This operator everted the whole organ, emptying the uterus and then amputating it at the level of the junction between the body and the neck. The peritoneum was secured about the cervix, and the stump of the cervix was exposed in the parietal incision. This operation definitely diminished the risk of peritonitis but involved the loss of the uterus and the shock attending so formidable a procedure. It is still occasionally used for its original purpose of avoiding peritoneal infection in cases in which the removal of the uterus is necessitated by a concurrent pathologic condition. In more recent practice it has been modified by peritonealizing the cervical stump and dropping it back into the pelvis.

About thirty years ago numerous technics were proposed for approaching the uterus beneath the perito-

Read before the Section on Obstetrics and Gynecology at the Ninety-second Annual Session of the American Medical Association, Cleveland, June 4, 1941.

neum, with the thought of lessening the risk of peritoneal infection and at the same time conserving the uterus. Out of those attempts there have evolved a number of operations, which fall into two types. The first type, true extraperitoneal operations, includes the Latzko operation, in which a paramedial incision is

made just above the symphysis, the bladder mobilized to the right (mainly by blunt dissection), the peritoneum displaced upward and the uterus entered by a vertical or a diagonal incision in the lower segment well down to the vaginal reflection from the cervix. The technic is not too difficult for any competent and experienced obstetric surgeon. It does, however, involve some danger of injuring the bladder near the base and some possibility of injuring the ureter. It is somewhat restricted in the space available for removal of the baby. In spite of these potential drawbacks, however, large babies have been successfully extracted by it, and our results with the operation have been exceedingly good in spite of a few technical accidents.

The only other type of true extraperitoneal section with which we have had experience is that developed by Waters in our clinic. In it the lower uterine segment is approached to the left of and above the bladder, a wide exposure of it being made through which a generous transverse semilunar incision can be made which permits easy extraction of even a large baby. The dissection in this operation is entirely away from the base of the bladder, the ureter and the large vessels of the parametrium. We have been highly successful

with it. Some of our staff prefer it to the Latzko operation, whereas others continue to use the Latzko.

A kind of compromise type of operations is represented by several technics of so-called peritoneal exclusion. In such operations the approach is by the peritoneal cavity, restricted areas of which are closed off by artificial approximation of parietal and visceral layers from the general cavity before the incision is made in the uterus. While the principles of these operations appeared relatively early, recent modifications of them

have been proposed from several clinics. Thus Irving reported the use of the Hirst operation, in which after vertical incision of the parietes the uterine and parietal layers are sutured to each other about a proposed vertical line of incision in the uterus, the peritoneal suture line being reinforced by a tier of fascial sutures. Cook approximated the round ligaments to the parietal peritoneum, thereby walling off a roughly quadrangular space low down on the uterus. Smith made his approach through a Pfannenstiell incision, incising the parieto-vesical and vesicouterine layers of peritoneum close to the bladder and completely amputating a small cap of peritoneum over the fundus of the bladder. These layers are then carefully sutured. The bladder is mobilized, and the uterus is approached by transverse incision through the lower uterine segment.

All the operations mentioned have the initial objection of opening the general peritoneal cavity widely, of being somewhat time consuming because of the extra amount of suturing used preliminary to opening the uterus and inviting in the case of Cook's operation a localized peritonitis which prolongs the hospital stay of the patient, and in operations of the first type of placing dependence on a suture line which readily tears with the extraction of the baby and the retraction of the

uterus. The introduction of the fascial tier of sutures in Irving's modification is directly necessitated by this risk.

Shortly after the attempts to develop true extraperitoneal operations, a number of surgeons attempted to refine the Sanger operation by approaching the uterus through the lower segment, where bleeding is less, where it is feasible to cover the incision by two layers of peritoneum and where the scar of the incision will not be so disturbed in future labors. Of all techniques developed on this basis the best known are those of De Lee, Beck, Munro-Kerr and Phaneuf. The bladder is mobilized from the lower uterine segment by incision through the vesicouterine peritoneum, and the lower uterine segment is incised vertically or transversely. We believe, in spite of the adherence of many capable operators to the Sanger operation, somewhat modified in most cases by a subumbilical incision of the parietes and by placing the uterine incision as low as possible without disturbing the relation of the bladder to the uterus, that the operations which most truly confine the incision in the uterus to the lower segment are preferable to those which involve mainly the corporeal segment. For this reason, in recent years we have preferred in most cases the transverse lower segment operation.

From what has been said in the foregoing brief sketch of the various operations concurrently in use in this

country, it is obvious that in general the transperitoneal operations are technically the simplest and therefore are to be chosen in preference to the slightly more difficult extraperitoneal types. Especially is this true when the time element is important with regard to the mother, as when she has severe hemorrhage, or to the baby, as

TABLE 5—*Maternal Mortality from Low Cervical and Extraperitoneal Section*

when prolapse of the cord occurs when rapid vaginal delivery is impossible and cesarean section is resorted to in effort to save the baby. Generally speaking, therefore, transperitoneal operations are to be chosen when the time of operation is elective as far as the duration of labor is concerned. This principle will generally apply in cases of disproportion sufficient to make the employment of cesarean section a predetermined matter; in cases of the hemorrhagic complications of labor, such as placenta previa and premature separation of the placenta; in cases of severe toxemia in which there has been no labor at all, and in similar situations.

Cesarean section has to be done, however, in many cases in which previous hope of successful vaginal delivery is disappointed in actual labor. In all such cases there is a greatly heightened risk of infection, on the basis of either neglect and injudicious handling or the mere duration of labor and the interval between the rupture of the membranes and the time of operation. The employment of any transperitoneal type of operation in these cases is inadmissibly dangerous, and the only safe recourse is to mutilating operations, such as the Porro operation, or to extraperitoneal section.

One may perhaps ask why in a well organized clinic there should ever be disappointment of the prognosis made prior to labor provided that prognosis was based on such care in prior examination as many physicians

believe to be within the competence of qualified obstetricians. We do not believe that absolute accuracy of prognosis is within the competence of any man. We believe this because in our own clinic a large number of patients are conscientiously and carefully subjected to all due scrutiny by a staff of alert, well trained, experienced obstetricians. Any one of us would readily concede that any number of obstetricians might possess higher competence than his own. We are not ready, however, to concede that many obstetricians possess

higher practical competence than is represented by our combined resources. Our error approximates 20 per cent. In the 20 per cent of patients for whom our prognosis has been erroneous there are two groups. In the one to whom we have given a good prognosis not all are successfully delivered by the vagina. If we persisted in delivering all this group from below we would certainly lose babies which should survive. But it is not certain that some of them are undeliverable by the vagina until many hours of labor have passed. We cannot safely apply transperitoneal technics of cesarean section to them. Hence of necessity we have to resort to extraperitoneal section. The other group, for whom we may fear that vaginal delivery will not be reasonably possible, sometimes are delivered by the vagina. To subject all this group to elective section without some test of labor would certainly result in a large number of unnecessary operations. Therefore, in respect to fetopelvic disproportion, we seldom employ cesarean section without some trial of labor. In making this confession we have no apologies to offer but feel

that such a policy contributes definitely to the best interest of our patients.

We will briefly exhibit the results of the employment of the three types of section by us during the last eight years, an approximate incidence of 2.5 per cent. In connection with these brief statistics two considerations must be accepted:

1. They are presented on only a few bases, and no attempt is here made to adjust responsibility for deaths or to delete deaths from any cause whatever; moreover, gross statistics of morbidity do not exhibit relative desirability in relation to severity of morbidity.

2. There is no significant technical difference between the classic type of section, as defined in this paper and practiced by us, and the lower segment type, especially when a vertical incision is employed. (This is extremely important.)

In table 1 is exhibited a maternal morbidity of 44.1 per cent in 68 cases of classic section, in about nine tenths of which the operation was performed under absolutely elective conditions.

In table 2 is a more detailed exhibition of the morbidity from 637 low transverse sections, 510 of which included transverse incision of the uterus, 521 of which

were done under virtually elective conditions, i. e., without more than nine hours of labor with ruptured membranes. The average morbidity is slightly higher than that for classic section, but our distinct impression is that the severity of the morbidity is less.

In table 3 are shown similar morbidity statistics for extraperitoneal operations, about half of which were by the Latzko technic and the rest by the Waters technic. All the patients had been in labor with membranes ruptured for more than twenty-five hours, thus presenting a distinct difference as compared with the other patients, on whom operation was done early in labor. As is to be expected, the morbidity is definitely higher. It is significant, however, that in no case did the morbidity exceed ten days.

Table 4 shows the maternal mortality from classic section in 68 cases, amounting to 10.3 per cent. It is evident from this table that in all the fatal cases this type of operation was selected with reference to the condition of the mother, to shorten the time of operation, without reference to other considerations. Therefore the inordinately high mortality is not a valid index of the possibilities of classic section and will be excluded from further discussion.

Table 5 exhibits the maternal mortality from low cervical and extraperitoneal section. We believe that this table most significantly indicates the necessity for reserving all types of transperitoneal section for patients whose condition gives relatively favorable indications.

Table 6 shows the incidence of stillbirths after classic cesarean section: 19.12 per cent. The same observation applies to this incidence as was made with reference to maternal mortality from classic section, and no significance will be attached to it in our discussion or conclusions.

Table 7 gives the fetal mortality after low cervical and extraperitoneal cesarean section.

CONCLUSIONS

1. Modern indications for cesarean section are relatively broad but must be assessed by careful individualization of cases on the basis of sound obstetric judgment and careful consideration of conditions.

2. When conditions are relatively elective the transperitoneal approach is best, on the basis of greater rapidity and facility of technic.

3. Favorable elective conditions include complete lack of contamination, freedom from clinical evidence of infection, duration of total labor not in excess of twenty-four hours and duration of labor with ruptured membranes not in excess of eight to twelve hours.

4. When the transperitoneal approach is made under the foregoing conditions it is relatively immaterial whether the modern classic technic or a lower segment technic is employed. We believe, however, as a matter of mature observation, that the lower cervical technics result in smoother convalescence and in decidedly less danger of future rupture of the scar.

5. In cases in which the previously indicated conditions do not obtain, operation should be confined to the technics embracing extraperitoneal approach. The results of such technics, even in much-neglected patients, have been in our experience extremely good in relation to maternal mortality and morbidity and to fetal survival.

MORTALITY, EARLY AND LATE, FOLLOWING CESAREAN SECTION

FREDERICK H. FALLS, M.D.

CHICAGO

When in the course of pregnancy or labor it becomes necessary to consider delivery by cesarean section as the best way to minimize the danger which is present in an individual case, the various methods of delivery from below must be carefully compared in order to evaluate their dangers to mother and baby under the peculiar exigencies of the situation. A careful weighing of the possibilities for each method of delivery is mandatory in order to avoid unnecessary risk. This can be done effectively only by a physician thoroughly trained in obstetrics. It is possible for one with sufficient general surgical skill to operate on the mother, to obtain a live baby and to have the mother also survive. Practically, however, it is found that in many instances the operation might have been avoided if the strictest indications had been observed and operative intervention delayed until absolute necessity dictated it. Failure to observe these principles is reflected in increased maternal and fetal mortality.

A second important factor contributing to mortality among women who eventually are delivered by cesarean section is the pernicious, wishful thinking of obstetricians of the Micawber type, who are always waiting for something good to turn up in an obstetric case instead of making careful estimates of what the forces of nature have done and may do to bring about spontaneous delivery. Too often the medical attendant suffers from an acute subluxation of the wishbone until it displaces his backbone. Patients are often allowed to progress until they get into serious difficulty, and the dangers of cesarean section are enormously increased by failure to seize the golden opportunity to do the operation early under favorable circumstances in place of procrastinating until conditions for surgical success are at the vanishing point. It is especially irritating when timidity is permitted to masquerade as conservatism. The policy, then, should be to be wisely conservative until circumstances indicate that one's attitude is creating a more dangerous set of circumstances than existed before, at which time more radical treatment must be undertaken.

The mortality from cesarean section depends on a number of factors, which may operate singly or in combination to bring about the fatal result. The dangers which threaten the lives of the mother and the baby may be inherent in the operative procedure itself or depend on the conditions necessitating the operation or on certain complications arising during convalescence or later. In this discussion I shall quote few statistics, for although statistics are valuable from a historical standpoint they are usually dependent on a variation in material and technic so wide as to be of little practical value for comparison with results obtained in one's practice. On the other hand, the dangerous complications which result in mortality are the same universally, and their nature and avoidance will be the theme of this discussion, in which I shall consider both maternal and fetal mortality.

From the Department of Obstetrics and Gynecology, University of Illinois College of Medicine.
Read before the Section on Obstetrics and Gynecology at the Ninety-Second Annual Session of the American Medical Association, Cleveland, June 4, 1941.

Inherent in every cesarean section is the danger of hemorrhage not only at the time of incision into the uterus but immediately before and after operation. The severity of preoperative hemorrhage frequently may be gaged from the history of the patient or from the evidence presented by the visible loss of blood and from careful and repeated blood counts. In many cases the operation can with advantage be temporarily delayed until the acute anemia has been overcome in whole or in part by blood transfusion. If a continued hemorrhage indicates an immediate operation, concomitant blood transfusions can be given. All too often the preparations for transfusion are postponed until the serious condition of the patient forces the physician to recognize the necessity for transfusion. When this occurs panic and haste interfere greatly with speedy, efficient service and technic. Hence all pregnant women who bleed vaginally should have a complete blood examination, including erythrocyte, leukocyte and differential counts, together with estimation of the hemoglobin content, blood typing and cross matching with the blood of suitable donors as soon as possible after the appearance of the hemorrhage. Under circumstances in which blood transfusion cannot be arranged the intravenous use of pooled serum or acacia solutions is indicated; failing these, the injection of dextrose in 10 per cent solution in physiologic solution of sodium chloride is useful.

During operation a severe hemorrhage may unexpectedly occur immediately after delivery. This complication is especially to be feared if the placenta occupies a position in the anterior wall just under the uterine incision. This tendency is greatly reduced, in my experience, if as a prophylactic routine 1 cc. of solution of posterior pituitary is injected directly into the uterine muscle a few moments before it is incised. I have never seen serious shock follow such an injection, although the possibility has been pointed out by other investigators. After the birth of the baby the uterus should be stimulated by vigorous massage if it tends to relax, and it may be brought out onto the surface of the abdomen for this purpose if necessary. It is my custom to compress by Allis forceps the larger uterine sinuses found bleeding on the cut surface of the uterine incision, until sutures can be placed.

After the birth of the baby it is my custom to inject a dose of an active ergot preparation into a deltoid muscle to increase the uterine muscle tone. If slight bleeding persists the uterine cavity may be packed with gauze soaked in weak hot saponated solution of cresol and wrung out. One end of the pack is pushed through the cervix into the upper part of the vagina, from which it can be recovered in forty-eight hours. In rare cases in which the hemorrhage does not start until after the operation, when the patient has been returned to her room the cervix may be exposed with a speculum and steadied with a tenaculum, and a 10 yard (9 meter) strip of gauze which has been soaked in saponated solution of cresol and wrung out may be used to pack the uterine cavity. The vagina should also be packed tightly, as the packing may act by producing counter pressure against the uterine arteries or by reflexly stimulating uterine contractions. Because of the closed cervix this procedure is sometimes difficult or impossible to follow on primiparas who have not been in labor.

In cases of premature separation of the placenta in which the muscle fibers of the uterus have been dis-

sociated by the blood (uteroplacental apoplexy of Couvelaire), packing and the use of solution of posterior pituitary and ergot preparations are usually unavailing. In such cases supracervical hysterectomy is indicated as soon as it is determined that the uterus is incapable of contracting sufficiently vigorously to stop the postpartum hemorrhage after the removal of the baby and the placenta by cesarean section.

The fatal outcome is due in most instances to the failure of the medical attendant to recognize the nature of the complication promptly and to follow the diagnosis by swift and decisive action. In the obstetric department of the University of Illinois College of Medicine, for the past eleven years in 10,977 cases not a patient has been lost from this complication. As soon as the diagnosis is even probable, if conditions are unfavorable for immediate delivery from below the abdomen is opened, the baby and the placenta are removed and the uterus under the full stimulation of oxytocics is observed. If it responds by good firm contractions it is sewn up; if not, supracervical hysterectomy is done. There have been 144 patients whose condition was diagnosed premature detachment of the placenta, and 26 of these have been treated by cesarean section.

Repeated blood transfusions may be necessary in some cases, and therefore it is advisable to have more than one donor available. The well organized blood bank is a long step forward in preventing mortality.

Shock is not infrequently a cause of death after cesarean section. This may be due to loss of blood, prolonged and rough operating technic, nervous instability in the patient, especially if she is under 18, or exhaustion from pain and long labor. The onset of shock can usually be foretold if a close watch is kept on the blood pressure, and if appropriate measures are taken to combat it the danger can be minimized. Prophylactically, it is important to see to it that women in labor who may need a cesarean section have rest and sleep and that they do not become dehydrated. It is often a valuable procedure to postpone an indicated cesarean section for some hours if there is no emergency, until the patient can be built up by sleep, intravenous injections of dextrose and stimulants to help her withstand the operative shock. During operation careful handling of tissues, rapid smooth technic and limiting the loss of blood combine to minimize danger from shock. Postoperatively the patient should have blood replaced if the loss has been excessive and should be given oxygen and stimulants for weak cardiac action, such as digitalin, dextrose given intravenously, epinephrine or nikethamide in full doses. Caffeine with sodium benzoate has also proved useful for some patients after recovery from the immediate symptoms of shock. Close cooperation between the anesthetist and the surgeon should minimize the danger of shock. The anesthetist is in a strategic position to observe the earliest signs of shock and to acquaint the surgeon with the fact of its presence and is able to lessen the degree of shock by lightening the anesthesia as soon as it is safe to do so.

Occasionally massive collapse of the lung may result fatally during or after cesarean section. This complication can be treated by the aspiration of mucus from the bronchial tree through the bronchoscope. Forced breathing of a 30:70 mixture of carbon dioxide and oxygen by means of a pressure bag attached to an

anesthetizing machine is also of value. Forcing a few whiffs of the mixture into the lungs under pressure will frequently result in a violent cough, the expulsion of the mucous plug and reopening of the collapsed portion of the lung. The oxygen tent as a temporary

Fig. 1.—Uterus arcuatus. Postmature child. Transverse presentation and prolapsed cord with thin uterine wall.

expedient in the acute stage is valuable. Full cardiac stimulation is indicated.

Acute dilatation of the stomach is relatively frequent and may be a fatal postoperative complication of cesarean section. It is frequently associated with and part of paralytic ileus. It should be easily detected and can be treated by decompression of the stomach by the Wangenstein suction apparatus. The administration of stimulants in full doses is indicated. Prophylactically, the less the bowels are handled and the more rapidly and smoothly the operation is carried out the less tendency there will be for this complication to arise.

Since heart disease is recognized as an indication for cesarean section in some cases, cardiac failure may precede or follow operation. I believe that the danger of the operation hinges particularly on the degree of compensation manifest in a given case and how this may be influenced by medical management. If the condition is such that a few days rest in bed with proper elimination and cardiac stimulation results in restoring compensation, the patient will be a much better operative risk. When feasible, local anesthesia reduces the pulmonary irritation which may predispose to the development of pulmonary edema and pneumonia. The further the pregnancy can be carried the better the prognosis for the baby, up to the thirty-fourth week. A compromise may be necessary and operation performed between the twenty-eighth and thirty-fourth week if decompensation threatens the mother's life. When decompensation cannot be controlled before the infant is viable, I prefer emptying the uterus by vaginal cesarean section.

When pulmonary edema develops in a pregnant woman from any cause the first effort should be to remove the cause and reduce the edema. To this end fluids are restricted and rest in bed, administration of digalen and magnesium sulfate by mouth and inhalation of oxygen may be useful. In most cases operation may be deferred until after improvement in the pulmonary condition. The use of the Drinker apparatus in certain cases is of value before and after operation. If beginning pulmonary edema manifests itself early in the first stage of labor in a primipara it is usually better to operate at once and treat the edema postoperatively. The decompression of the uterus permits of much better ventilation of the bases of the lungs and improves the circulation by relieving pressure. If, on the other hand, the edema first appears during labor in a multipara, the dilatation of the cervix can usually be hastened by the use of manipulation, or Dührssen incisions may be employed with advantage to complete it. However, if even a moderate pelvic contraction is present it may be safer to do a cesarean section with the aid of local anesthesia.

Hypertension without convulsions increases the danger of pregnancy and labor by predisposing to serious toxic symptoms which may lead to a fatal outcome. Cerebral hemorrhage occurs in some cases, and anuria and uremia may be present and difficult to control. When the indication for cesarean section is not of an emergency character the patient should be put to bed and treated for the hypertension for at least a week before one resorts to surgical intervention. The operation is best done with local anesthesia without the use of epinephrine. In the majority of cases if the hypertension is associated with chronic nephritis the interests of the patient are best subserved by the performance of sterilization at the time of operation. On the other hand, if the hypertension is rapidly advancing and of the eclamptogenic toxemia type and convulsions are imminent cesarean section, best done with local anesthesia, is imperative. When convulsions are present the seizures may cause extrusion of some of the abdominal viscera through the wound and may interfere seriously

with proper suture of the uterine and abdominal wounds, thus increasing the operative time, the danger of infection and the loss of blood. I feel that under these circumstances cesarean section with ethylene anesthesia is indicated. The technic should be especially guarded with regard to asepsis, since the patients stand

Fig. 2.—Placenta previa centralis. Absolute indication if fetus is viable. Danger of fetal death if labor starts is obvious.

When convulsions are present the seizures may cause extrusion of some of the abdominal viscera through the wound and may interfere seriously with proper suture of the uterine and abdominal wounds, thus increasing the operative time, the danger of infection and the loss of blood. I feel that under these circumstances cesarean section with ethylene anesthesia is indicated. The technic should be especially guarded with regard to asepsis, since the patients stand

infection poorly. Loss of blood up to 500 cc. should be encouraged if the patient is not anemic, since bleeding has long been known to be of value in such cases. One of the most important points in the postoperative management is to keep the patient to a strict dietary

Fig. 3.—Previous cesarean section. Rupture may occur before or after onset of labor. Thinning and stretching of uterine scar and adhesions of bowel and omentum create special operative hazards.

regimen until the blood pressure has become reduced and the casts and albumin in the urine begin to disappear.

I wish it clearly understood that I do not advocate cesarean section for patients with eclamptogenic toxemia except those in whom the toxemia cannot be controlled by medical management, especially if they are primiparas, or in whom the symptoms develop in a fulminating manner which does not permit a trial of medical management. In a series of 1,000 cases of eclamptogenic toxemia, 37 mothers have been delivered by cesarean section with no deaths; of these, 12 had eclamptogenic toxemia of the convulsive type. Again I would stress the importance of decisive action. Procrastination and indecision are the cause of the mortality in such cases, not cesarean section. Naturally it does not take long for the rapidly shifting clinical picture to develop to a stage at which the cerebral edema, hepatitis, nephritis and myocarditis make operative intervention virtually the same as manslaughter.

Sometimes a patient with an acute infection outside the generative tract must have a cesarean section to save her life, the life of the baby or both. Fortunately such patients are extremely rare, but one does well to remember that they do exist and must be cared for. If the infection is not too near the midline of the abdomen the dangers of directly contaminating the peritoneal cavity are not great. The prophylactic removal of the uterus by Porro section is recommended, because it

automatically removes the danger of puerperal sepsis and so leaves one with but one danger (peritonitis) to combat instead of two. The prophylactic use of immune serum and of sulfanilamide derivatives (about 60 to 80 grains [4 to 5 Gm.] a day) is desirable and should be started immediately after operation.

Occasionally the bladder or the bowel is injured during cesarean section. The accident is not so serious as a rule if the hole is found and carefully repaired. The patient is given a urinary antiseptic, and an indwelling catheter is kept in the bladder for twelve days. Injury to the bladder is most likely to follow the low cervical and Porro operations. When injury is suspected but not proved, a catheter should be passed and the bladder distended with boric acid solution containing methylene blue to reveal the location of the hole. Peritonitis from an unrecognized injury of the bowel or extravasation of urine from an overlooked injury of the bladder may be fatal.

Ruptured membranes increase the danger of cesarean section because of the increased likelihood of bacterial contamination of the uterine cavity. The mother is jeopardized primarily because of the possibility of infected uterine spill contaminating the peritoneal cavity and starting general peritonitis and secondarily because puerperal sepsis may develop in the uterus and spread to other parts of the body. Again the time element is all important. Operation within a few hours after rupture entails practically no additional risk. After the fourth hour, however, the danger rapidly increases. As a corollary, therefore, one may say that given a patient who may have to be delivered by cesarean section one may view with complacency the early stage of labor as long as the membranes remain intact. However, with their rupture the situation should be carefully

Fig. 4.—Placenta on anterior wall. Dangers: increased loss of maternal blood owing to vascularity at site of incision. Fetal hemorrhage from incision of placental vessels.

and critically studied and the decision to deliver by cesarean section elected or rejected and the treatment followed through on the lines given here. Neglect of this precaution will lead frequently to fatal complications even though ultimately a Porro cesarean section is done to minimize the danger from infection. At best

this is a makeshift procedure designed to salvage something from a serious situation produced too often by neglect or by ultraconservatism. In the presence of frank infection one should seriously consider a craniotomy, even though the heart tones may be thought to be present, if the fetus seems to be in bad condition and a high forceps operation fails after moderate traction.

I believe cesarean section is practically always indicated for central placenta previa and for the other types as well when the antepartum hemorrhage is profuse and the mother is in danger therefrom. In cases of partial separation in which there is only moderate hemorrhage and the fetus is just viable the decision to do a cesarean section or to deliver from below is a difficult one. If the patient is in labor she may be permitted to go on under close observation and a cesarean section performed if the heart tones become rapid or weak. If she is not in labor I give progesterone to inhibit uterine contractions and try to keep labor and hemorrhage from recurring until the baby is fully viable, at thirty-two to thirty-four weeks. Such management is justifiable only for hospitalized patients.

Pulmonary embolism is a rather infrequent complication after cesarean section. I feel that it is practically always associated with infection and that all patients who show evidence of thrombophlebitis of the broad ligament or the femoral veins should be kept at absolute bed rest for twenty-one days or until one can be reasonably sure that the clots in the femoral and iliac vessels have had time to organize sufficiently so that they will not be dislodged.

FETAL DANGERS

Various complications of labor as far as the fetus is concerned may indicate cesarean section. When prolapse of the cord occurs in a primipara with a cervix only a few centimeters dilated delivery by cesarean section is much safer. The danger lies in the fetal asphyxia which is apt to be present before the patient is operated on.

Nephritic toxemia in the mother not infrequently results in premature intrauterine fetal death. This regrettable accident is entirely unpredictable according to my experience. Abdominal hysterotomy should be done as soon as it is felt that the baby has a good chance of surviving after birth (at about the thirty-fourth week).

Habitual death of the fetus is a condition which requires the nicest judgment to determine when to invade the uterus and deliver a live baby. No premonitory signs or symptoms are present. One has to rely on the history to tell when one may expect the death of the fetus and act before this accident occurs.

Another danger to the fetus results from cutting of the large vessels of the placenta or the cord when the incision in the uterus overlies the site of placental attachment. Serious hemorrhage into the amniotic cavity from the fetal circulation may occur unless the baby is rapidly extracted and the cord compressed.

Acute placentitis often results in fetal septicemia, which frequently is fatal to the baby even if it is extracted by cesarean section. This complication most frequently follows premature rupture of the membranes.

Death of the mother as the result of either accident or disease should always be an indication for cesarean section if a viable fetus is present. When it is obvious that the mother is dying it may give the fetus a better

chance if one performs the operation before the death of the mother than if one waits until she dies. Permission should always be obtained for this operation, but I have twice performed it without the permission of the family in an emergency, after hurried consultation with other physicians present, and have saved the infant each time.

Several hours after delivery babies extracted by cesarean section not infrequently have cyanotic spells which gradually deepen and finally end in death. The cause is obscure. Potter has found an unusual amount of cerebrospinal fluid and has expressed the belief that this may produce pressure on the respiratory center. Oxygen inhalations and stimulants are indicated but are not very effective in combating the condition.

Occasionally a cesarean section is undertaken, usually by a general surgeon in consultation with a general practitioner, even when labor has progressed to the stage at which the fetal head is deeply engaged. Under these circumstances serious injury may be done to the baby from forcible efforts at extraction of the head from the pelvis after the uterus is open. I know of 2 cases in which the baby was decapitated, and in both the mother died from hemorrhage before leaving the operating room. It is well, therefore, to be sure the head is not deeply engaged or can be disengaged before one attempts cesarean section.

Rupture of the scar from a previous cesarean section is practically synonymous with fetal death, and there is no practical way to prevent it except through anticipating the rupture by doing a second cesarean section before the rupture occurs. Unfortunately the accident can occur before the woman has had any labor pains. It rarely occurs, however, until after viability of the baby is established. Therefore if there is a history of febrile convalescence from the first operation one may assume a weakness of the scar and do a cesarean operation prophylactically after the fetus becomes fully viable.

The maternal mortality from this form of rupture of the uterus is low compared with that of rupture during labor. Because of the cicatricial nature of the edges of the rupture hemorrhage is not a serious complication as a rule.

A study of the records of the pathologic department of Cook County Hospital shows the outstanding cause of maternal mortality in cases in which cesarean section is done to be ruptured uterus.

CONCLUSIONS

It will be seen that the mortality from cesarean section both early and late for the mother and the baby is dependent not so much on the operation as on the indication for which the operation is undertaken and on the proper time of the operation in relation to the onset and course of the complication. In certain instances quick, decisive action is imperative, even in the presence of serious complications which under ordinary conditions would contraindicate major surgical procedures. In other circumstances conservatism until the patient can be placed in the best possible shape for major surgical intervention is indicated.

Careful evaluation of the factors involved in all complicated obstetric cases should be made, if possible, prior to the onset of labor and a plan of action outlined which will be thoroughly understood by the patient as well as

by the attending physician and his associates. Only in this way can one avoid the dangerous situations which arise because of unwarranted procrastination and are responsible for the greater percentage of deaths both maternal and fetal which are charged to cesarean section at the present time.

30 North Michigan Avenue.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRs. COSGROVE AND NORTON AND DR. FALLS

DR. LOUIS E. PHANEUF, Boston: Drs. Cosgrove and Norton have emphasized the most important factor in cesarean section, namely individualization of the patient. While the classic operation may be a satisfactory method for the clean patient, it cannot be employed with the same safety in the contaminated gestant. The several procedures described were devised in the course of years as experience increased. I myself use the low flap operation in all clean cases; the peritoneal exclusion technic, of which there are two varieties—the Veit-Fromme-Hirst, with a longitudinal incision in the uterus, and the recently devised Erwin F. Smith technic with a transverse incision in the lower segment, for the presumably infected woman. The extraperitoneal procedure, either the Latzko or the Waters operation, is used for the frankly infected patient, and finally the temporary exteriorization of the uterus, the Gottschalk-Portes operation, or the Porro operation in the badly neglected parturient. Whether one makes a transverse or a longitudinal incision in the lower segment is a matter of individual preference. I favor the transverse incision. By following the recommendations presented in the paper, that is, proper selection of operation, maternal mortality in cesarean section could be reduced to its minimum figure. Dr. Falls has covered the causes of early and late mortality in cesarean section. The three outstanding causes of mortality have been, from the earliest times of the operation, hemorrhage, sepsis and pulmonary complications. Hemorrhage has been controlled to a great extent by prophylaxis on the one hand and by blood transfusions on the other. The replacement of blood has become a very simple procedure. The blood is usually administered without even moving the patient from her bed. If we go back a little more than two decades we find that then the blood transfusion was more of an operation than the cesarean section itself, showing the marked improvement in the replacement of blood. Improvements from infection have come through two avenues: (1) from the better understanding of obstetrics, resulting in operating early in labor, before contamination has occurred, and (2) by choosing the proper method for a given case, as exemplified in the first paper. There is hope that the sulfonamides may still further aid in reducing the infections of childbirth. Pulmonary complications can be reduced by the more general use of local infiltration anesthesia in the performance of abdominal delivery. While the technic is more meticulous and slightly more time consuming, both patient and obstetrician are rewarded by the smoother convalescence and the reduced complications.

DR. H. HUDNALL WARE JR., Richmond, Va.: My associates and I use the low classic operation in the elective cases when the patient is not in labor, and our results in this group have been good. If one decides to deliver a patient by abdominal operation under other circumstances, a careful estimation of a number of factors must be made before the type of procedure is selected. The type of operation should depend on the patient's general physical condition, age, the number of children and the amount of manipulation, with attendant trauma and possibly infection to which the patient has been subjected during labor. The low cervical or double flap operation is preferred in cases in which the membranes have ruptured, active labor has started or unquestioned sterile vaginal examination has been made. In probably or obviously infected patients and in all patients in whom unsuccessful delivery has been attempted from below, either the extraperitoneal or a modified Porro operation should be performed if abdominal delivery seems necessary. At the Medical College of Virginia Hospitals during the past five years,

30 patients have been delivered either by the modified Porro operation or by cesarean section followed by hysterectomy. There was only one death in this group, and autopsy showed that this patient had a severe pyelonephritis. The newer types of cesarean operations have reduced the mortality rate for operative cases, but the modified Porro operation still has a definite place for a small group of neglected obstetric patients.

DR. JOSEPH B. DE LEE, Chicago: The frequency of cesarean section in this country is out of all proportion to the necessities and contributes largely to our continuing high maternal mortality, although, in general the country over, the mortality is being reduced. The cesarean operation has partaken of that improvement which all surgical procedures have enjoyed, and that is one of the reasons doctors resort to it so often. I was hoping that I would live to see the day when craniotomy on the living child would be obsolete, but that is not yet true. Cases in which craniotomy on the living child are indicated are very few in number compared with the olden time. The essence of Drs. Cosgrove and Norton's paper was the difference between the intraperitoneal and the extraperitoneal approach to the lower uterine segment in cases of infected labors. In 1920 to 1929 we had much discussion about the values of these two operations, the Latzko extraperitoneal and its modifications, and the direct transperitoneal or intraperitoneal approach that Veit, Froome, Sellheim, Beck and others have perfected. At that time we found that the difference in mortalities was not significant, that the peritoneum would take care of a lot of infection and that the connective tissue was not any more resistant to infection than the undamaged but closed peritoneal cavity. However, perhaps there might be a little greater advantage in the extraperitoneal approach. Local anesthesia was mentioned by Dr. Falls. I think that local anesthesia should be the method of choice in all cases, and of cesarean section particularly. The shock which Dr. Falls mentioned I have found present only in women who are likely to have shock from other causes than the operation—heart disease, pulmonary affairs and toxemias. In a woman who hasn't these conditions, shock is very rare under local anesthesia. At the Lying-in Hospital in Chicago we have had about 1,500 cases under local anesthesia. We have yet to see a massive collapse of the lung. In fact, we have had no deaths from anesthesia in over 1,500 cases of local anesthesia in cesarean section. I feel, in spite of the wonderful results shown by Drs. Cosgrove and Norton, that spinal anesthesia has inherent dangers which make it unwise when one can do the same operation just as well with local anesthesia. Of the difference between the old classic and low cervical cesarean section, I feel that the old classic cesarean section should, with almost no exception, be called obsolete. If, however, one feels that one must do an old classic cesarean section, I would recommend the low operation modified by Dr. Schumann of Philadelphia, in which he makes a flap, a sort of little trap door, in the lower part of the uterus and then, pushing the cover of the door aside, makes the incision.

DR. JAMES F. NORTON, Jersey City, N. J.: We have nothing much to offer in closing. I agree with Dr. De Lee that there is a lot to say about cesarean section. We presented just one phase, the management of women long in labor, with membranes ruptured, with the presenting part fixed at the inlet, not engaged, who have had sometimes many vaginal examinations, many rectal examinations, and on whom occasionally an unsuccessful attempt has been made to deliver through the birth canal. We are confronted with that problem all too frequently, and to circumvent the disastrous consequences of transperitoneal section we have utilized, in quite a number of cases, an extraperitoneal approach to the lower uterine segment. We offer for comparison a morbidity study of the low cervical, the classic and the extraperitoneal group, and we feel that we have something that serves us well in a very difficult situation. Since our clinic was opened we have had about 50,000 women. We have not done one craniotomy on a living child; it is passé as far as we are concerned. Of the four deaths in the extraperitoneal group of cesarean section, in a study of 209 patients I was in labor for fifty-four hours with ruptured membranes had an intrapartum rise in temperature to 103.4 F. before she was operated on and under any obstetric management at all

would have been a very formidable problem. One death, I think, is related to the operation, severance of a ureter and general sepsis, but at postmortem examination I think the strongest argument we have for utilizing the true extraperitoneal type of incision came from this case of severance of a ureter in an individual who had previously a pyelitis, that is, an intrapartum pyelitis. The peritoneal cavity was not infected. The patient died of general sepsis but did not have a proved peritonitis at postmortem examination. We had one death from hemorrhage, and hemorrhage is inherent in all cesarean section problems. We had one death which has been called acute heart failure for want of ability to define it more accurately; it might well have been any number of things. We were not able definitely to assess truly the cause of the death. That death and the hemorrhage death and the death of the woman long in labor may have occurred from any type of operation, which really leaves us with one death truly assessable against an extraperitoneal infection, and that in an individual who at postmortem examination did not have a peritoneal infection.

DR. FREDERICK H. FALLS, Chicago: I did not discuss the cause of fetal mortality in the paper. The prolapse of the cord in an undilated cervix is the important reason for cesarean section from the standpoint of the fetus. In partial premature detachment of the placenta, if the hemorrhage is only minor and stops, it is best to allow the woman to go on and take the chances of delivery from below, but, with a continual trickle of blood and not knowing what is going to happen to the placenta, I feel that cesarean section is the best way out of the difficulty. As soon as the membranes rupture, a new element enters the obstetric case and the case should be reevaluated. The question of a moderately contracted pelvis, and of toxemia, coupled with early rupture of the membranes should mean that the case is reevaluated in the light of the new accident, which may be the determining factor in delivering the patient by cesarean section instead of from below. Another factor which occurs in causing mortality is pulmonary embolism, which in my opinion is always due to infection. The infection many times is low grade, and it is a thrombophlebitis of the veins of the pelvis and is often overlooked. So, given a woman having a low grade temperature, with a moderate tenderness in the region above Poupert's ligament, I watch the patient very carefully until satisfied that there is no thrombophlebitis of the veins. There is some question as to whether continuous or interrupted suture is the best method of repair after the low cervical operation. I have used the continuous suture many years. In closing, it is a pretty thin piece of uterine muscle and in the presence of hemorrhage there is a tendency for the operator to pull the suture tight to stop the hemorrhage. The hemorrhage is not occurring from that wall; it is bleeding from inside the uterus, and it doesn't make any difference how tight you pull these sutures, it won't stop the hemorrhage, and if you pull them tight there is the possibility of a slough in that uterine wound.

The Human Factor in Aviation.—Man has manufactured a machine to which he is inferior so far as operating efficiency is concerned. To a certain extent, rules set up to govern his action overcome the difficulty. . . . But rules cannot be devised which will insure proper action in every emergency. Ultimately such action will depend on the good judgment of particular men, and what the aviation industry is trying to do is make sure that its pilots are the sort of men who will exercise good judgment. It is trying to devise physiological and psychological methods by which it will be able (1) to select the proper persons as pilots, (2) to maintain them at their maximum efficiency and (3) to eliminate those who fall below an established level. Pilots must be absolutely normal men, physically, mentally and spiritually. The industry is trying to find standards for choosing such men and determining whether they remain so. So far it has been successful only in certain respects. Here is the problem of research in the human factor in aviation. —Fatigue of Workers, Report of Committee on Work in Industry of the National Research Council, New York, Reinhold Publishing Company, 1941.

THE MILLER-ABBOTT TUBE IN SURGERY

OCTA C. LEIGH JR., M.D.

AND

RICHARD O. DIEFENDORF, M.D.

NEW YORK

Since the introduction of the Miller-Abbott¹ principle of intubation of the small bowel for the management of ileus by Abbott and Johnston,² the morbidity and mortality in our series of cases of this disease has been reduced to an all time low figure.³ Although often eliminating some surgical procedures, the technic should not be considered as a nonoperative method of treatment but rather as an adjunct to proper surgical care.

We continue to advise immediate operation in cases of strangulated hernia or other obvious early mechanical obstructions with mild distention and, of course, all cases suspected of gangrene of the bowel. Continuous gastric or duodenal suction and other simpler therapeutic measures are still used in many cases of mild involvement in which there is moderate distention, particularly in the early postoperative period. In the cases reported here either mechanical obstructions were demonstrated at operation or distended loops of small bowel with fluid level formation appeared when viewed radiographically.

OBSTRUCTIONS OF THE SMALL BOWEL

The immediate therapeutic problem in noninflammatory obstructions of the small bowel, either paralytic or mechanical, is the restoration of fluid balance and body nutrition while distention is controlled and an accurate diagnosis is made. We have classified as "paralytic obstructions" all cases in which a mechanical obstruction was not demonstrated by intubation of the small bowel. It is recognized that sufficient motor activity is present after deflation to pass the Miller-Abbott tube along the entire length of the small bowel. The term is retained, however, since it is generally accepted by the profession and it is our impression that active peristalsis is either absent or greatly depressed before deflation is accomplished.

Our cases in the paralytic group were associated with lesions of the spinal cord due to trauma or infection, retroperitoneal hemorrhage or infection, pneumonia, renal stones and surgical trauma of the abdominal viscera and included a few cases that appeared to be either augmented by or caused by edema of the bowel.

The group of cases thought to be due to edema of the bowel was of considerable interest, since this factor is not generally recognized. Two occurred in the early postoperative period in patients having a low plasma

protein who had been given large quantities of intravenous physiologic solution of sodium chloride. In 1 case 8 liters and in a second case 11 liters of fluid was aspirated through the Miller-Abbott tube from the upper part of the gastrointestinal tract during the first twenty-four and thirty-six hours respectively. The depressed motor activity of the intestine was evident by the extremely slow progress of the tube through the bowel.

Recently a man aged 51 was admitted to the hospital for extensive second and third degree burns of the right side of the body. On the fourth hospital day there was severe abdominal distention (fig. 1), nausea, vomiting and generalized edema. His total body weight had increased 6 pounds (2,722 Gm) and the plasma proteins had decreased from 7.11 to 5.50 Gm. per hundred cubic centimeters. Proctoscopic examination revealed pale, edematous mucous membrane of the rectum and lower part of the sigmoid flexure having the general appearance of mucosa after the submucosal injection of saline solution. The Miller-Abbott tube was passed into the upper part of the

injected through the tube to identify the exact location and often the nature of the obstruction. Small inflammatory adhesions or knuckles of bowel which prolapsed into small defects in the peritoneum in the early postoperative period have been demonstrated in many

2 feet (61 cm) during the first two days of intubation, passed rapidly into the transverse colon as the edema and ileus disappeared.

Heretofore, the administration of barium sulfate by mouth in cases of ileus has been of little value to the radiologist. The opaque medium was so diluted by the fluid accumulated in the distended proximal loops of intestine that it was practically useless. Now, after deflation, small amounts of barium suspension can be

to a partial or recurrent obstruction, the tube may act as an ileostomy over a prolonged period while the patient is adequately prepared for operation by oral feedings. If the resection of a pathologic loop is necessary, the preliminary deflation is extremely helpful. The distended proximal loops are reduced to almost normal size before resection is attempted and the anastomosis protected postoperatively by maintained decompression.

Two hundred and nine cases of noninflammatory obstructions have been subjected to intubation, with 11 deaths, or a mortality of 5.3 per cent. Two of the deaths listed as "paralytic obstructions" occurred in cases of terminal renal failure and death resulted from uremia after partial deflation had been accomplished. Five of the deaths in the mechanical group occurred in cases of generalized carcinomatosis in which death occurred after the obstructions had been relieved. The mortality for ileus alone in this group was 4 deaths in 202 cases, or approximately 2 per cent.

OBSTRUCTIONS WITH ALL VARIETIES OF PERITONITIS

It is our impression that obstructions secondary to an inflammatory process in the peritoneal cavity may be either paralytic or mechanical or both. We con-

sider this group of cases separately, since the therapeutic problem is immediately changed by the presence of the infectious process. The dramatic improvement that follows successful intubation seems to indicate that deflation improves the circulation of the bowel and prevents spread of the infection. A comparison of the mortality in the cases in which intubation was accomplished successfully (table 2) with the cases in which the tube failed to pass the pylorus shows the advantage of prompt deflation.

Most of our failures occurred in this group of seriously ill patients. We used to hesitate to subject these patients to the added discomfort of repeated fluoroscopic examinations but we now feel that the results more than justify the procedure.

Localized abscesses or early peritonitis often involves and obstructs the small bowel either by inflammatory edema per se or by causing angulations that result in mechanical obstructions (fig. 2). Prompt deflation allows adequate food and fluids by mouth until the

bowel interferes with the circulation and leads to edema, poor motor activity and decreased absorptive function of the bowel. When pressure is applied along the suture line of a fresh anastomosis it may lead to tissue ischemia, necrosis, leakage of intestinal contents and the formation of fistulas or peritonitis.

Before Miller-Abbott tube, 1936-1937....	13	9	69.2
After Miller-Abbott tube, 1938-1940.....	20	11	55.0

In our experience, patients requiring resection of the colon or rectum and those with serious infections of the peritoneal cavity are most likely to have these complications develop. If intubation is delayed until extreme distention has developed, the passage of the tube into the small bowel is always difficult and sometimes

Fig. 2—Acute diverticulitis with localized peritonitis and acute ileus. A, plain roentgenogram of abdomen with colon filled with barium sulfate showing distended loops of small bowel. B, after deflation the tube arrested in the region of localized peritonitis. Barium injected showed a partial obstruction thought to be due to angulation of the bowel involved in the inflammatory process. C, the tube at the cecum five days later. The obstruction disappeared as the infection subsided.

infection subsides and the temporary obstruction is relieved. If the distention is allowed to persist, the distended loops are fixed in abnormal positions by fibrous adhesions that often lead to permanent obstructions (fig. 3).

PROPHYLACTIC USES OF THE MILLER-ABBOTT TUBE

Intubation of the small bowel is equally important to the surgeon in the prevention of distention in a selected group of cases in which the disease or operation may cause prolonged impairment of gastrointestinal activity. Distention occurring within the lumen of the

impossible. On the other hand, intubation is relatively simple if done before operation or early in patients with peritonitis before distention has occurred. We therefore advise prophylactic intubation in these patients.

Our results in a small but well controlled group of consecutive cases of radical resections of the colon and rectum for carcinoma seems to indicate that preoperative intubation with maintained decompression in the early postoperative period has reduced the mortality by avoiding some of the serious complications often encountered in these cases.

The use of chemotherapy, improved anesthesia, controlled fluid therapy and the vitamins has improved the results in all our cases during the past few years. The improvement is most striking, however, in the cases in which the tube was passed before operation and decompression was maintained until normal bowel function was reestablished.

Our attending surgeons agree that prophylactic decompression is ideal in the one stage operations of the ascending colon. The arguments in favor of the two stage operation of the ascending colon were based on the dangers of leakage from the ileocolostomy done at the time of resection. With the maintenance of

deflation before and after operation, the one stage procedure is now safer because it eliminates the dangers of two operations and two anesthetics as well as the difficulties often encountered with inflammatory adhesions at the second operation.

For lesions of the descending colon or rectum with uncontrolled distention on admission, cecostomy appears to be the treatment of choice. Prophylactic intubation in these cases is of course unnecessary. If no distention is present, the preliminary cecostomy can be avoided by use of the tube. Although a relatively simple operation, cecostomy may cause serious infections and often prolongs the period of hospitalization at least two or three weeks. The results in this group appear to justify our impression that some of the serious complications can be avoided. Our attending surgeons, however, have not accepted prophylactic decompression in the descending colon and rectal cases as enthusiastically as in cases of the ascending colon.

It is even more difficult to present clearcut data to show our impression that maintained decompression has prevented some of the complications that usually follow serious infections of the peritoneal cavity. Here again other factors have contributed to a general improvement of all our cases, but the following figures appear significant:

In the 1,075 cases of acute appendicitis with associated lesions treated during the five year period before the introduction of the Miller-Abbott tube (1933-1937 inclusive), 6.75 per cent (68 cases) were classified as diffuse or generalized fibropurulent peritonitis, with a mortality of 20.6 per cent. Of the 726 cases under treatment since the introduction of the Miller-Abbott tube (1938-1940 inclusive), 3.4 per cent (25 cases) were classified as diffuse or generalized fibropurulent peritonitis, with a mortality of 12 per cent. In other words, our complicated cases occur about one half as often, with approximately one half the previous mortality.

OBSTRUCTIONS WITH GANGRENE OF THE BOWEL

We continue to advise immediate operation in all cases suspected of gangrene of the bowel. Our criteria for suspecting gangrene are (1) a history of the sudden onset of pain that persists between the attacks of crampy, colicky pain, (2) localized tenderness or a palpable mass and (3) an elevated temperature, pulse and white blood cell count which do not return to normal after adequate fluids have been administered.

The mortality in this group continues at the same high figure as before the introduction of the Miller-Abbott tube. Three of the deaths occurred in cases in which there was profound shock when first seen, too late for any type of treatment.

Operations were unfortunately delayed on 3 patients in spite of the fact that several of the criteria for gangrene persisted after partial deflation and administration of adequate fluids. One is lulled into a false sense of

security by the temporary improvement which follows intubation of the small bowel. Deflation can be extremely helpful if used intelligently during the short preoperative period required to prepare these patients for operation and in the usually stormy postoperative period that follows. Gangrene should be suspected on admission, and the apparent improvement that follows should not cause the surgeon to overlook his original diagnosis.

Gangrene of the bowel is an admitted hazard to intubation of the small bowel. However, this type of case comprises only 5 to 10 per cent of the total cases of ileus and is not a valid excuse for depriving the remaining 90 to 95 per cent of the cases of the advantages to be gained by it.

COMMENT

Intubation of the small bowel can be most successfully accomplished if it is supervised by some members of the staff familiar with the method. We do not wish to imply that the technic requires special training, but it does require considerable time and careful attention. In

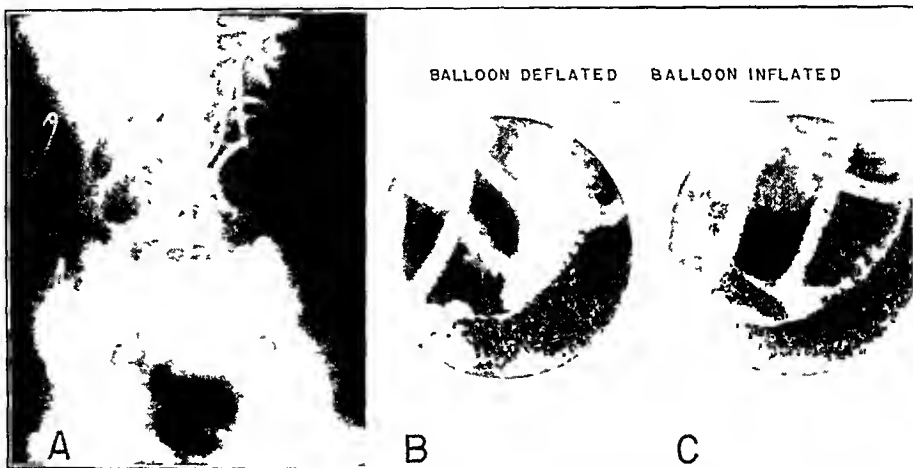

Fig 3—Generalized peritonitis with permanent obstruction following acute appendicitis. A, Plain roentgenogram of abdomen on eleventh hospital day showing Miller Abbott tube arrested in left lower quadrant. Pressure roentgenograms at the point of obstruction after the injection of barium. B, with the balloon deflated and C, the balloon inflated. Patient maintained in satisfactory nutritional state by continuous suction and oral feedings until fibrous adhesions were divided at operation on thirty fourth hospital day.

this hospital, one of the senior surgical residents and one of our graduate nurses have been assigned to the patients requiring intubation in the various parts of the hospital. With the constant cooperation of the members of the department of radiology, we have now attempted

Fig. 4.—Radical resections of colon and rectum for carcinoma.

more than four hundred intubations with less than 10 per cent failures.

The busy surgeon of today is not expected to do the detailed work required for successful intubation, but

he must know that intubation of the small bowel cannot be successfully accomplished by haphazard attempts within a short period of time. A lack of understanding on the part of the attending surgeons has been responsible for the slow acceptance of this important contribution to abdominal surgery.

SUMMARY

Intubation of the small bowel in cases of intestinal obstruction has diagnostic and therapeutic value. Our mortality and morbidity rates for this condition have reached an all time low since the introduction of the Miller-Abbott tube.

2. Figures presented show that maintained decompression will reduce the mortality in cases of radical resection of the colon and rectum, and our impression is that maintained decompression will prevent the serious complications of serious infections of the peritoneal cavity.

3. Gangrene of the bowel continues to be an admitted hazard to intubation of the small bowel, but the possible harm that may be done in this small group of cases is not a valid reason for depriving the greater percentage of cases presenting obstructions of the advantages gained by its intelligent use.

630 West 168th Street.

ABSTRACT OF DISCUSSION

DR. GROVER C. PENBERTHY, Detroit: When the use of the long tube was first advocated by Johnston and Abbott there was skepticism in the minds of a great many because of the danger of relying on the Miller-Abbott tube as a possible cure-all for intestinal obstruction. There can be no doubt about the efficacy of the suction drainage by the Miller-Abbott tube in the great majority of acute and chronic obstructions and the obstruction due to adynamic ileus. The tube can never replace surgical treatment. If the diagnosis of strangulation is made, the treatment should be early surgical exploration, especially with the history of acute onset of pain in the abdomen, localized tenderness and recurrent colic-like pain. There should be no delay except to allow for a minimum of time for hydration, blood or plasma infusions. The immediate important problem is not the distention, although that may be troublesome. The primary difficulty is the inadequacy of the mesenteric blood supply. This can be accomplished only by surgical intervention. On the other hand, simple adynamic ileus should not be treated surgically. In a paper presented before this section in 1938 by our group it was stated that "the advantages of the method in properly selected cases are as follows: 1. It carries the patient past the period when operation is most dangerous. 2. It prepares the patient for operation by control of distention, thus making operation less traumatic for the patient and easier for the surgeon. 3. It affords a means of localizing the site of obstruction and frequently indicates its nature. 4. It permits oral feeding of the patient during a period when food and fluid are so essential and frequently has permitted us to improve the patient's nutritional state during the period of treatment. 5. It releases the tension above the site of obstruction and frequently reestablishes the normal passage of intestinal contents, thus permitting the patient to be operated on in the interval stage if advisable. 6. In the treatment of paralytic ileus this is the only method we know which can uniformly be depended on to relieve the distention of the small bowel, which is not uncommonly fatal. The disadvantages of the method are that: 1. It necessitates careful selection and evaluation of cases. It is not suitable for treatment of strangulated types of obstruction. 2. It requires hard work on the part of the surgeon and his associates. Passage of the tube and attention to details with regard to the patient and the equipment require continued attention. 3. It is not suitable for obstruction of the large bowel, since, despite the fact that the tube frequently traverses the entire intestinal tract, it cannot be depended on to reach the large bowel quickly enough to be of value."

ACUTE HEMOLYTIC STREPTOCOCCUS
INFECTIONS COMPLICATING
ADDISON'S DISEASE

TREATMENT WITH SULFADIAZINE AND ADRENAL
CORTEX EXTRACT; REPORT OF TWO CASES

GEORGE W. THORN, M.D.

AND

ROGER A. LEWIS, M.D.

BALTIMORE

The susceptibility of patients with Addison's disease to acute infections of the upper respiratory tract is well known.¹ Despite the efficacy of adrenal cortex extract² in maintaining patients in good clinical condition, a relatively high incidence of infections of the upper respiratory tract, especially those caused by the hemolytic streptococcus, persists.

During the past year eight severe acute hemolytic streptococcus infections have occurred in a group of 50 patients with classic signs and symptoms of Addison's disease. The clinical course of the infection in all 8 patients was characterized by an abrupt onset with temperature rising to 104-106 F. within the first twelve to twenty-four hours. A striking fall in blood pressure usually occurred within the first twelve to thirty-six hours. Little or no leukocyte response was noted in the 4 patients who were hospitalized. Two of these patients died as a direct result of the streptococcic infection.

Sulfanilamide and sulfathiazole were used in the treatment of the 2 patients who died. It was thought that these drugs might prove efficacious, but unfortunately the toxicity of these compounds for patients with Addison's disease precluded their continued administration. From the clinical course of these patients, however, it seemed apparent that the newer and more potent adrenal cortical hormone preparations in conjunction with intravenously administered dextrose and saline solutions could be depended on to maintain plasma volume, blood pressure and blood dextrose level and thus prevent the early death (twenty-four to forty-eight hours) which so frequently terminated acute adrenal crisis. Thus, if an effective bacteriostatic of relatively low toxicity was available, one might reasonably hope for some success in treating this serious complication with combined glandular and antibacterial agents.

Recently we have had an opportunity to use sulfadiazine³ in conjunction with adrenal cortex extract in the treatment of acute hemolytic streptococcus pharyngitis in 2 patients with Addison's disease (charts 1 and 2). The absence of nausea, vomiting and other toxic manifestations during treatment with sulfadiazine permitted adequate chemotherapy. The clinical response of these 2 patients was so striking in comparison to our previous experience in the treatment of this complication that we are recording in some detail the therapeutic measures which were employed.

Dr. Lewis is John D. Archbold Fellow-in-Medicine.

Dr. W. Barry Wood gave many valuable suggestions.

From the Chemical Division, Medical Clinic, the Johns Hopkins University and Hospital.

This study was aided by a grant from the Committee on Research in Endocrinology, National Research Council.

1. Rowntree, L. G., and Snell, A. M.: A Clinical Study of Addison's Disease, Mayo Clinic Monographs, Philadelphia, W. B. Saunders Company, 1931. Greene, C. H.: Clinical Use of Extract of the Adrenal Cortex, Arch. Int. Med. 59: 739 (May) 1937. Greene, J. A., and Johnston, G. W.: Electrolyte Balance During Treatment, Crises and Severe Infection in Cases of Addison's Disease, *ibid.* 66: 1052 (Nov.) 1940.

2. Thorn, G. W.: Treatment of Addison's Disease, Clin. Endocrinol. 1: 76 (Jan.) 1941.

3. The sulfadiazine that was used in these studies was supplied by Dr. Perrin Long.

The purpose of treatment may be summarized as follows:

1. Support of plasma volume and blood pressure:
 - (a) Intravenous infusion of sodium chloride (0.9 per cent solution) and dextrose (5 per cent solution).
 - (b) Aqueous adrenal cortex extract (intravenously and subcutaneously).
 - (c) Synthetic desoxycorticosterone acetate in oil (intramuscularly).
 - (d) Epinephrine in oil, intramuscularly.
2. Prevention of hypoglycemia:
 - (a) Intravenous infusion of dextrose (1a).
 - (b) Frequent feedings of readily available carbohydrate.
 - (c) Treatment with adrenal cortex extract to increase gluconeogenesis (1B)⁴
3. Antibacterial chemotherapy:
 - (a) Intravenous administration of sodium sulfadiazine.
 - (b) Oral administration of sulfadiazine.

SUGGESTED OUTLINE OF THERAPY

1. Five hundred cc. of 0.9 per cent sodium chloride solution and 1,000 cc. of 5 per cent dextrose solution are given intravenously and repeated every eight hours (at the time of the initial venipuncture, blood is with-

Chart 1—Temperature and blood pressure of first patient. The initial dose of sulfadiazine was 4 Gm. of the sodium salt administered intravenously. The first dose of adrenal cortex extract was also given intravenously.

drawn for hematocrit, blood sugar, serum chloride and bicarbonate determinations).

2. Twenty-five cc. of aqueous adrenal cortex extract is added to the intravenous infusion and in addition 10 cc. of extract is injected subcutaneously. The subcutaneous injection of 5 to 10 cc. of aqueous extract is repeated every two to three hours until the fever subsides.

4. Thorn, G. W.; Koepf, G. F.; Lewis, R. A., and Olsen, Elizabeth F.: Carbohydrate Metabolism in Addison's Disease, *J. Clin. Investigation* 19: 813 (Nov.) 1940.

3. Twenty mg. of desoxycorticosterone acetate in oil is injected intramuscularly in divided doses during the first twenty-hour hours, and 5 to 15 mg. given once daily thereafter.

4. Sodium sulfadiazine 4 to 5 Gm. is given intravenously. It is extremely important to administer the

Chart 2—Temperature and blood pressure of second patient. The initial dose of sulfadiazine was 4 Gm. of the sodium salt administered intravenously. The first dose of adrenal cortex extract was also given intravenously.

sodium sulfadiazine intravenously, as every effort should be made to establish an adequate blood level of the drug as rapidly as possible. Following this, 1 Gm. of sulfadiazine is given every four to six hours by mouth and the blood level is maintained at 10 to 20 mg. per hundred cubic centimeters as long as fever persists. If the oral dose is not retained, the blood level is maintained by giving 2 Gm. of sodium sulfadiazine intravenously at eight to twelve hour intervals. Frequent determinations of the blood level of the drug are indicated because of the strong fluctuation in fluid balance which may occur in these patients. It is also desirable to continue sulfadiazine therapy in smaller doses for five to seven days after the temperature has returned to normal (charts 1 and 2).

5. One cc. of epinephrine in oil injected intramuscularly at eight to twelve hour intervals is indicated if the level of systolic blood pressure is below 100 mm. of mercury.

6. Blood pressure determinations are made at intervals of one to two hours, day and night. Small quantities of fruit juice with added lactose, or ginger ale, are given at frequent intervals, if tolerated. Since 1,500 cc. of saline and dextrose solution is given intravenously every eight to twelve hours during the first two days, additional fluid by mouth is not essential. A daily blood specimen is taken for hematocrit, nonprotein nitrogen, blood sugar and sulfadiazine level. Hemodilution, excessive edema or hypertension is a definite indication for temporarily discontinuing injections of

desoxycorticosterone acetate in oil and for reducing the amount of intravenous saline solution. On the other hand, hypotension, if accompanied by hemoconcentration, is a definite indication for increasing the dosage of desoxycorticosterone acetate in oil and the quantity of saline solution administered intravenously. If hypotension and generalized edema occur at the same time, it is wise to discontinue desoxycorticosterone acetate in oil therapy and resort to frequent injections of aqueous adrenal cortex extract (10 cc. every one to two hours). One cc. of epinephrine in oil may be injected intramuscularly and repeated if the systolic blood pressure continues to fall. Our experience with the unfavorable reaction of some patients with Addison's disease to transfusions suggests that this therapeutic procedure be withheld unless other measures fail.

SUMMARY

Acute hemolytic streptococcus infections continue to be one of the most frequent and serious complications which occur in patients with Addison's disease. Adequate sulfadiazine therapy was well tolerated by 2 patients with acute hemolytic streptococcus pharyngitis. The use of this drug in conjunction with adrenal cortical hormone appears to offer the most efficacious form of treatment now available for patients with Addison's disease with this type of infection. An outline of the therapy is given, and the urgent need for immediate, constant and continued treatment is indicated.

PROTOCOLS

1. E. L.,⁵ a woman aged 52, single, who had had Addison's disease for over two years, was in the Johns Hopkins Hospital for treatment of arthritis. On May 18, 1941, 5 pellets which had been implanted eleven months before were removed. Two days later the patient contracted a fever which was thought to be due to a recurrent cystitis. She was given a small dose of sulfathiazole but no additional therapy. The next morning her temperature had risen to 105 F. and her throat had become inflamed and edematous. Her blood pressure fell from 140 systolic and 80 diastolic to 78 systolic and 50 diastolic mm. of mercury and she became semicomatose. An infusion was started immediately and she was given 1,000 cc. of 5 per cent dextrose and 500 cc. of 0.9 per cent sodium chloride solution. She was also given 4 Gm. of sodium sulfadiazine intravenously and 1 Gm. of sulfadiazine by mouth. During the first twelve hours of treatment she received 55 cc. of aqueous adrenal cortex extract intravenously and subcutaneously, 15 mg. of desoxycorticosterone acetate in oil intramuscularly and 1 cc. of epinephrine in oil intramuscularly. With continued treatment the temperature gradually fell and the blood pressure returned to normal thirty-six hours after therapy had been instituted. Her convalescence was complicated by an attack of erythema nodosum.

The essential laboratory data were as follows:

On March 19, the initial date of infection, the hematocrit reading was 38.5 per cent volume of packed cells, the white blood cells 12,700, blood nonprotein nitrogen 30 mg. and blood dextrose 81 mg. per hundred cubic centimeters, the serum chloride 99 and the serum carbon dioxide combining power 28.5 milliequivalents per liter. A urine culture taken at this time was reported as being sterile; a throat culture revealed 85 per cent beta hemolytic streptococci. On March 20 the blood level of free sulfadiazine was 21 mg. per hundred cubic centimeters. On March 21 the white blood cells were 10,400. March 22 the hematocrit reading was 32.7 per cent volume of packed cells. On March 23 the throat culture showed normal throat flora.

2. A. H., a woman aged 21, married, who had been treated for Addison's disease for one year, was admitted to the hospital for reimplantation of pellets of desoxycorticosterone acetate. On the morning of May 16, 1941 she did not feel well

and complained of a sore throat. At 4 p. m. the same day her temperature was 105 F. At this time the pharynx was inflamed and the tonsils were large and swollen. Treatment was immediately instituted, 4 Gm. of sodium sulfadiazine being given intravenously and 1 Gm. of sulfadiazine every four hours being given orally. At the same time she was given 15 mg. of desoxycorticosterone acetate in oil and frequent subcutaneous injections of adrenal cortex extract in addition to saline and dextrose infusions intravenously. During the first twelve hours of treatment the temperature remained elevated and the swelling and redness of the throat increased. Despite the presence of moderate generalized edema the blood pressure fell from 115 systolic and 75 diastolic to 72 systolic and 48 diastolic mm. of mercury. At this time 1 cc. of epinephrine in oil was given intramuscularly. During the second twelve hours of treatment there was a remarkable improvement in her general condition and during the second twenty-four hours of treatment the temperature fell to 98.6 F. (rectal) and the blood pressure gradually returned to normal.

The essential laboratory data were as follows:

On May 16, the initial date of infection, the white blood cells were 10,200 with polymorphonuclears 64 per cent, lymphocytes 29 per cent, myelocytes 6 per cent and eosinophils 1 per cent. A throat culture showed 75 per cent beta hemolytic streptococci. On May 17 the white blood cells were 8,200 and the blood level of free sulfadiazine was 10 mg. per hundred cubic centimeters. On May 19 the blood level of free sulfadiazine was 9 mg. per hundred cubic centimeters and on May 20 a throat culture revealed only normal throat flora.

DIAGNOSTIC AND PROGNOSTIC VALUE OF THE ELECTROENCEPHALOGRAM

FREDERIC A. GIBBS, M.D.

BOSTON

Twelve years have passed since Berger¹ first described the electrical beat of the brain in man. In these twelve years workers all over the world have studied intensively the anatomic, physiologic and psychic correlates of the electroencephalogram.² More than six hundred articles dealing with this subject have been published and sufficient evidence has been accumulated to indicate the general significance of this new phenomenon and to show that it has practical value for the solution of clinical problems, and also that it has certain definite limitations.

Before proceeding further, I shall define electroencephalography: It is the technic of recording the electrical beat of the brain. As Berger pointed out, this beat is analogous to the beat of the heart as it appears in the electrocardiogram. The brain beat is entirely electrochemical, however; it has no appreciable mechanical component. In the normal waking state the brain does not beat as a single huge unit but as many small, more or less independent units with ill defined boundaries—somewhat like the heart in fibrillation. The voltage ordinarily obtained from the brain is about one hundredth as large as that obtained from the heart, which makes vacuum tube amplification necessary. Another difference between the electroencephalogram

From the Department of Neurology, Harvard Medical School, and the Neurological Unit, Boston City Hospital.
Read before the Section on Nervous and Mental Diseases at the Ninety-Second Annual Session of the American Medical Association, Cleveland, June 6, 1941.

The investigations of the author have been supported by grants from the Rockefeller Foundation, the Josiah Macy Jr. Foundation and by WFA projects 17579 and 22203.

1. Berger, Hans: Ueber das Elektroencephalogramm des Menschen. I. Mitteilung, Arch. f. Psychiat. 87: 527-570, 1929.

2. It is impossible in this short report to include references to the work of all those who have contributed to our present knowledge of the subject. A complete bibliography and proper distribution of credit will be found in the Atlas of Electroencephalography by F. A. Gibbs and E. L. Gibbs (Cambridge, Mass., Lew A. Cummings Company, 1941).

5. The complete protocol appears in Thorn, Koepf, Lewis and Olsen.⁴

and the electrocardiogram is that the complex wave forms in the electroencephalogram, unlike those in the electrocardiogram, cannot be interpreted as due to the spread of a wave of excitation. In the electroencephalogram, complex waves are the result of superimposed beats from different types of functional units, for the brain is far from a homogenous organ—some units are large and some small, some slow and some fast. Another important difference should be noted: The electroencephalograph does not record activity at any great distance; only activity going on immediately under an electrode shows in the record. If electrodes are connected to the front and back of the head, for example, what is recorded is not the beating of the entire brain but the algebraic sum of the activity under the frontal electrode and under the occipital electrode.

The beating of the brain becomes faster and shallower with stimulation, and particularly with attention. It slows and develops a high amplitude with deep sleep. It becomes faster with increasing age and varies greatly from one person to another. It is about as labile as the facial expression but, like facial expression, tends to remain more or less characteristic for each individual. All this variation in normal subjects, however, makes interpretation difficult.

Diseases of the brain tend to produce definite disturbances in the brain beat, but unless the cortex immediately under the electrodes is disturbed abnormalities will not appear in the record. Thus it is difficult to detect and impossible to localize deep cerebral or cerebellar lesions. It is true, however, that a localized lesion may set off abnormal nerve impulses which produce a focus of disorder in a distant cortical field. On the other hand, if there are no functional connections extreme injury in one part of the brain may not manifest itself at all in another. The response of the brain to injury is in general nonspecific: Injury usually produces abnormally slow waves, and the worse the injury the slower the waves. At times, however, injury produces bursts of abnormally fast waves. The location of a brain tumor, area of trauma or a localized infection may be deduced from the part of the cortex that shows maximal disorder. When a lesion is truly cortical, such localizations are about 90 per cent accurate. As has been said, however, deep cerebral lesions and cerebellar lesions are ordinarily unlocalizable. Instead of the usual type of electrode that is pasted on the surface of the head, a nasal electrode has been recommended for localizing lesions at the base of the brain, but as yet no adequate series has been collected to show how accurate such deep localizations are. Electroencephalography has these advantages over the injection of air and roentgenography. It is absolutely painless and perfectly safe. On the other hand, in the general run of brain tumors it does not give as accurate a localization as the injection of air and roentgenography. Nevertheless, when used by a competent diagnostician, it can save a certain number of patients the necessity of the injection of air, and in some cases in which, despite all other procedures, a satisfactory localization cannot be arrived at, the electroencephalogram will provide crucial evidence leading to a correct localization. The over-all accuracy of the electroencephalographic localization of gross intracranial lesions is about the same as the accuracy of localization from the neurologic examination.

Probably the greatest economic advantage of electroencephalography lies in its usefulness in cases of head injury. Such cases not only form a large fraction of

neurologic practice but they are beset with various legal complications which make the clinician feel acutely the need for an objective record of function of the central nervous system. Such a record is provided by the electroencephalogram. It can show the extent to which function of the central nervous system has been impaired, the imminence of convulsions and whether the patient is improving or getting worse.

In various conditions in which the nature of the disease is known and also the general areas that are involved, it is nevertheless desirable to know the extent and degree of cortical involvement. In Sydenham's chorea, for example, cortical involvement is fairly common, but in any given case the neurologist may wish to know whether this has occurred. So also with epidemic encephalitis and meningitis.

In all the conditions mentioned thus far electroencephalography is used as an auxiliary technic. In the diagnosis and understanding of epilepsy electroencephalography is of primary importance. Epilepsy is associated with extreme and obvious modifications of the cortical beat not only at the time of a seizure but in intervals between seizures. In grand mal attacks the beat becomes too fast, in psychic seizures it is too slow and in petit mal attacks there is a kind of gallop rhythm, a three per second alternation between fast and slow. Unfortunately, about 10 per cent of the supposedly normal population has cerebral dysrhythmias, and these are only slightly or not at all different from the interseizure dysrhythmias of epileptic patients. Thus it is hazardous to make a diagnosis of clinical epilepsy from the electroencephalogram. I believe, however, that these cases of asymptomatic dysrhythmias are in fact cases of asymptomatic epilepsy. Only the severest dysrhythmias in a person are clinically evident and only especially severe cases of cerebral dysrhythmia in the population manifest themselves as clinical epilepsy. When the incidence of convulsions is higher than that in the normal population, for example, in the parents and near relatives of epileptic patients or in the lowest grades of feeble-mindedness, the incidence of dysrhythmias is proportionately higher.

Severe cerebral dysrhythmias are at times encountered in persons with an unusual type of gastric complaint. This finding suggests that the difficulty is cerebral rather than gastric. Cases of uncontrollable rage or negativism at times show exacerbations of cerebral dysrhythmia correlating with the outbursts. Many problem children show abnormalities similar to those encountered in epileptic patients with psychic seizures. The physician can make practical use of these facts if he considers the possibility that almost any type of bizarre behavior may be the result of cerebral dysrhythmias. The behavior in some cases, however, is not so bizarre. Occasional cases of stuttering are due to petit mal, and also cases of inattention or gross carelessness. Extreme belligerence or abusive speech which might be considered normal is at times a manifestation of a psychic seizure.

In the treatment of epilepsy, the electroencephalogram is helpful because it tells the amount and type of disorder that is present. On the amount of disorder depends the chance of successful therapy. On the type of disorder depends whether phenobarbital or sodium diphenyl hydantoinate is likely to be more useful. In all cases, however, the only way to tell which therapy will work best is to try them. The final treatment of epileptic patients is much the same in a clinic with

an electroencephalograph as in one without. The advantage for the former lies chiefly in greater ease and accuracy of diagnosis and classification and a better comprehension of the basic features of this condition.

Thus far little has been said about what electroencephalography cannot do. It cannot at present be used to diagnose manic-depressive psychosis, schizophrenia, feeble-mindedness, migraine or psychoneurosis. It cannot detect loss of brain substance unless the mass of tissue which has been lost is very large, for what is recorded is activity, and when a part of the cortex has died and ceased to function it is hardly missed in the great welter of activity that still remains.

What is the future of electroencephalography? It will be used in an increasing number of clinics and hospitals, as at present it is being used for the diagnosis of cortical dysfunction and the localization of intracranial lesions. But new uses will appear as more quantitative data are obtained. A method devised by A. M. Grass makes it possible to transform the electroencephalogram from a complex mixture of waves into a chart showing the exact amount of energy in each frequency. With such quantitative data, it is easy to consider a statistically significant series of cases, to establish standards of normal and abnormal and to show degrees of correlation. Thus, it will be seen that quantitative electroencephalography is now possible. This development is likely to be of more practical importance for the psychologist and the mental tester than for the physician. Work now in progress, however, indicates that with greater refinement in technic and better standards of normal certain characteristic abnormalities will be found in schizophrenia.

SUMMARY AND CONCLUSIONS

The electroencephalogram is of clinical value in:

Epilepsy for diagnosis, localization, prognosis and regulation of treatment.

Narcolepsy for diagnosis.

Brain tumor for diagnosis and localization.

Subdural hematoma for diagnosis and localization.

Brain trauma for diagnosis, localization and prognosis.

Brain abscess for diagnosis and localization.

Meningitis for prognosis (residuals).

Encephalitis for diagnosis and prognosis.

Sydenham's chorea for prognosis (cortical involvement).

Schilder's disease for diagnosis.

Behavior disorders for diagnosis and prognosis.

The electroencephalogram at present has only negative value in schizophrenia, manic-depressive psychosis, feeble-mindedness, migraine and psychoneurosis.

Interpretation of the electroencephalogram is difficult because of the complexity and variability of the wave forms in a given person, the variation with age and the wide range of patterns within a given age group.

In the future, electroencephalography will be increasingly applied to clinical problems. Accumulated data will make interpretation easier and more accurate. Quantitative analysis will establish standards for different ages and sexes and will probably reveal significant abnormalities in patients with schizophrenia and some other conditions which at present are supposed to be unassociated with abnormalities in the electroencephalogram.

Boston City Hospital.

ABSTRACT OF DISCUSSION

EDWARD J. BLADES, PH.D., Rochester, Minn.: Dr. Gibbs has pointed out the value of electroencephalography from a diagnostic and prognostic point of view. Although the first publication on electroencephalography by Berger dates back only twelve years, the bibliography of more than six hundred articles is indeed indicative of the thought and energy with which the subject is being explored, and it is no exaggeration to say that many thousands of electroencephalograms are at present being studied in an endeavor to evaluate fully the clinical use of electroencephalography. To those interested in becoming better acquainted with the various types of electroencephalograms I recommend the "Atlas of Electro-Encephalography" published about three months ago by Dr. and Mrs. Gibbs. Dr. Gibbs and his group in Boston have been particularly interested in the study of dysrhythmias and cortical dysfunction, whereas at the Mayo Clinic more attention has been paid to the possibilities of the localization of lesions by electroencephalography. In our experience the electroencephalogram has proved to be of definite value in the diagnosis and prognosis of epilepsy and has been applied, for example, in follow-up examination of some patients who have petit mal epilepsy and are on a ketogenic diet. In regard to the detection and localization of deep cerebral and cerebellar lesions, my colleagues and I believe that many lesions of this type can be localized approximately by examining the electroencephalogram for delta activity that appears bilaterally. For instance, tumors of the posterior fossa are usually associated with bilateral delta activity in the occipital, parietal and temporal areas. This, of course, presupposes that a deep seated lesion can cause a disturbance in the cortex, as the electrical activity actually recorded is only from areas approximate to the electrodes. It is our practice to place sixteen electrodes on the head, in the frontal, motor, anteroparietal, postparietal, occipital, cerebellar and temporal areas, on both sides of the head and both ear lobes, to record routinely on four channels from twenty to thirty minutes and to use both bipolar and monopolar leads. These records are proving to be most useful for study and it is only by the examination of complete records that electroencephalography will be able to maintain the pace already set in the first twelve years of its existence.

DR. MICHAEL M. MILLER, Lexington, Ky.: Since it is well known that the prognostic determinations in cases of functional psychoses and neuroses depend a great deal on the extent of deterioration of the intelligence, I should like to ask Dr. Gibbs whether this method has been studied with regard to the question of determining the extent of cerebral deterioration.

DR. FREDERIC A. GIBBS, Boston: I am glad that Dr. Blades pointed out that it is difficult to localize deep lesions by the technic of electroencephalography as ordinarily employed. I have found it impossible to localize deep tumors or cerebellar tumors. This is because with the usual leads only the activity of the cortex is recorded. Various injuries in the basal ganglia, for instance, although associated with very evident clinical disorders, show no abnormalities at all in the electroencephalogram. Dr. Blades told us that workers at the Mayo Clinic are using the finest possible discrimination on records from cases in which there are deep lesions in the effort to see whether something cannot be found in the electroencephalogram which will allow localization of the lesion. They recognize that they will have to use quite different criteria from those which we and they have used in localizing cortical lesions. It is encouraging to hear that they are meeting with success. They cannot as yet tell us what their accuracy with deep lesions will be, but they have told us that in localizing cortical lesions they have an 80 or 90 per cent accuracy. In order to answer Dr. Miller's question I will read a list of the conditions in which the electroencephalogram is of clinical value. It is definitely useful in epilepsy, brain tumor, concussion, brain trauma, subdural hematoma, encephalitis, meningitis and brain abscess; it is of some value in thyroid disease, cerebral arteriosclerosis, narcolepsy, behavior disorders and dementia paralytica. It is at present of no practical value in schizophrenia, manic-depres-

sive psychosis, multiple sclerosis, parkinsonism (when there is no cortical involvement), choreoathetosis, migraine, psychoneurosis and undifferentiated feeble-mindedness, and when I get to undifferentiated feeble-mindedness I get to the point which Dr. Miller brings up. It is extraordinary what severe degrees of dementia can occur with a normal appearing electroencephalogram, and it is incorrect to suppose that for every psychic change there is some electroencephalographic equivalent. Continuous very slow waves may be found in a man who is standing at the top of his class and a normal record in an individual who has never learned to cat and has never spoken. There are some tremendous discrepancies, and we must continue our study in order to find out just what is at the basis of them. For what at present may seem like annoying inconsistencies may, when explained, prove to be the key to a better understanding of central nervous function.

Clinical Notes, Suggestions and New Instruments

ANAPHYLACTIC SHOCK WITH HEMOCONCENTRATION TREATED INTRAVENOUSLY WITH SALINE SOLUTION

HARRY BLOTNER, M.D., BOSTON

The subject of shock, whether it is surgical or medical, is of unusual interest today. Recently I treated a patient in severe anaphylactic shock. The picture resembled so closely that of surgical shock that it appears of interest to present the details of this case. Ordinarily the treatment of anaphylactic shock is not considered in relation to the blood picture, as it is in cases of surgical shock. I believe that the treatment, based on hemoconcentration and decreased blood volume, was effective and that the method used is of practical significance.

It is generally regarded now that an essential feature of shock is a relative decrease in the circulating blood volume compared with the size of the vascular system. Such an inequality may be brought about by a loss of fluid from the circulation or by an increase in the size of the vascular bed. When fluid is lost a concentration of the blood results, which may be noted by an increased count of the red blood corpuscles or by an elevated hematocrit reading. Excellent reviews of this subject have been given recently by Moon,¹ Dunphy,² Stead³ and Janeway.⁴

LITERATURE

There have been reports in the literature showing an increased concentration of the blood and a decreased volume of blood in cases of anaphylactic shock. Dean and Webb⁵ reported an increase in the hemoglobin content and red blood cell count during anaphylactic shock in dogs. Wyman and tum Suden⁶ noted reductions in the plasma volume in rats depending on the severity of the anaphylaxis. In 1 rat, the plasma volume was reduced 63 per cent in sixty-two minutes after injection of serum. Simonds⁷ found hemoconcentration and decreased blood volume during anaphylactic shock and during intoxication with peptone in dogs. Drinker and Went⁸ found a low blood volume

in guinea pigs with severe anaphylactic shock which, however, they believed was due to poor mixing of the injected dye. Eppinger and his associates⁹ found an increased erythrocyte count incident to acute urticaria. Black and Kemp¹⁰ observed an increased specific gravity of the blood during an acute reaction to ragweed pollen in man and during anaphylaxis in guinea pigs, the degree of which paralleled the severity of the reaction in the animals. Meyler¹¹ reported hemoconcentration in 2 cases of extensive serum disease in man. In the first instance a patient with ulcerative colitis was given large quantities of antidysentery serum and an extensive serum rash and a clinical picture of shock developed, during which the red blood cell count rose from 4,500,000 to 6,000,000. It was impossible to determine the blood volume, because when congo red was injected it disappeared from the blood into the urticarial wheals, which became fiery red. This was a good demonstration of increased permeability of vessels. In the second case of ulcerative colitis general urticaria and shock developed fifteen minutes after a transfusion. The red blood cells increased from 3,900,000 to 7,000,000 during the period of shock. Anaphylaxis may be regarded as an example of true shock, and its circulatory phenomena have been ascribed to increased capillary permeability by Manwaring and his associates,¹² Seegal¹³ and Lewis.¹⁴

REPORT OF CASE

A. F., a man aged 22, was seen for the first time on July 24, 1941 in consultation with Dr. J. J. DiSalvo at the Clover Hill Hospital, Lawrence, Mass., because of severe anaphylactic shock. The entire history of the patient is irrelevant except that about three or four years before he had received a dose of tetanus antitoxin. He had had no cardiac irregularity when examined by his physician on previous occasions.

July 24 at 12:10 p. m. the patient was given as a prophylactic 1,500 units of tetanus antitoxin intramuscularly. He stayed at the physician's office for about twenty minutes and had no apparent ill effects. The patient then went about his routine and at 1:30 he felt an itch in the suprapubic region and noticed what looked like a small blotch. Two minutes later a blotch appeared on the forehead, which was followed by a rash on the whole face. He went back to his physician at 1:55. His face, arms and feet became swollen and a rash developed over the body. At 2:15 he received 5 minims (0.3 cc.) of epinephrine subcutaneously. He became unconscious but the urticaria and the swelling diminished. In about five minutes it was necessary to administer ten minims (0.6 cc.) of epinephrine subcutaneously. The patient was cold and clammy and perspired profusely. The pulse was not perceptible. The blood pressure was 30 systolic and 0 diastolic or less. In another few minutes he was given again 10 minims of epinephrine intravenously and he improved very slightly. Shortly thereafter he became worse and 10 minims of epinephrine was injected intravenously on two occasions. In addition, there were administered an ampule of nikethamide by injection and ephedrine sulfate 50 mg. orally. The blood pressure increased to about 80 systolic and 40 diastolic. The patient was not alert. Vision was blurred. He had nausea and pain in the epigastrium and vomited several times. He was sent to the hospital at 5 o'clock by ambulance because of his critical condition. On arrival, he was given 1,000 cc. of 10 per cent dextrose intravenously and later ephedrine sulfate 25 mg. by this route.

Physical examination at 8:30 showed that the patient was critically ill and was gasping for breath. The pulse was rapid and thready, with a rate of about 160 a minute. The blood pressure was 50 systolic and 30 diastolic, with some variations above and below this level. The heart sounds were weak and a rare extrasystole was present. Murmurs were not heard.

The lungs showed no rales. The abdomen was normal. The reflexes were normal. The liver and spleen were not palpable. The arms, hands and feet were noticeably edematous. The arms were about one and one-half times their normal size. There was an urticarial rash over the body. A puncture wound was present on the sole of the left foot. The patient obviously was in severe anaphylactic shock.

Because of the possibility that there might be some similarity between anaphylactic shock and surgical shock and that this might be noted by the concentration of blood, a red blood count was made immediately and this was found to be 6,910,000. The hemoglobin level was 100 per cent + (Tallqvist). Because of this hemoconcentration, physiologic solution of sodium chloride was given intravenously immediately. When 500 cc. had been introduced into the circulation, the patient began to feel better. The blood pressure began to rise to a level of approximately

* Red blood cells recorded in millions; white blood cells ranged from 7,000 to 12,200; other serum percentages were:

	Albumin	Globulin	Nonprotein Nitrogen	Chloride
July 28.....	3.5 Gm.	2.0 Gm.	29 mg.	330 mg.
August 15.....	3.4 Gm.	3.8 Gm.	21 mg.	424 mg.
August 21.....	4.8 Gm.	2.6 Gm.	37 mg.	321 mg.

100 systolic and 70 diastolic and the pulse rate began to drop to 110. One liter of saline solution including 10 cc. of 10 per cent calcium chloride was given intravenously in fifty minutes and frequent examinations of the lungs showed no rales. Subsequently, another liter of saline solution was given intravenously, and during this period also no rales appeared.

The 2 liters of saline solution was administered continuously from 9:35 to 11:30 p. m. During this time epinephrine 1 cc. was given subcutaneously. By 11:30 the pulse dropped to 108, the blood pressure rose to 118 systolic and 70 diastolic and the patient appeared considerably improved. During the night red blood cell counts were made. At 11:55 the red blood cell count had dropped to 5,700,000, at 5:30 a. m. to 5,000,000 and at 11:15 to 4,610,000. During the night frequent blood pressure readings were taken and they showed some variations. The patient's mind was rather blank during the period of acute therapy, although he does remember that he was short of breath, that it was difficult for him to breathe and that he knew he was getting injections.

Theoretically, it would be ideal to give plasma in a state of shock without hemorrhage, because there is a considerable loss of plasma from the circulation. It might have been even more effective than saline solution in this case, since there is evidence for the loss of plasma in anaphylaxis. However, it was not

given in this instance because saline solution could be administered without delay and after saline solution was given plasma was not needed.

On July 25 the patient appeared much improved. The rash had almost disappeared, although he still had some edema of the hands and lips. The pulse was between 90 and 110 and the blood pressure was 118 systolic and 50 diastolic. The lungs were clear. The heart was normal except for rare extrasystoles. The reflexes were normal. The patient's progress in the hospital was satisfactory. He took orally ephedrine sulfate 50 mg. twice a day until August 4. For the first few days he complained of frontal headache and dizziness when raising his head from the pillow. An occasional blotch appeared periodically until shortly before discharge. On and after July 27, the blood pressure varied from 100 to 130 systolic and 50 to 70 diastolic and the pulse from 84 to 60. On July 28, a frequent irregularity of the heart developed consisting of extrasystoles, and two days later he had some dull precordial pain of less than fifteen minutes' duration. Roentgenograms of the chest were negative on August 9. He was discharged from the hospital feeling well on August 16. Subsequently, he has been active and well, although he has continued to have rare extrasystoles.

LABORATORY DATA

The various laboratory data obtained are presented in the accompanying table. It was of interest to find that the patient's blood was concentrated during the stage of shock and then dropped to normal in a few hours after treatment with saline solution intravenously and remained at a normal level during his stay at the hospital. It was interesting, too, that the serum protein which was determined on July 28 was diminished to a level of 5.5 Gm. per hundred cubic centimeters. Subsequent determinations showed the serum protein to rise as the patient progressed and improved until it reached a level of about 7.4 Gm.

Electrocardiograms, 4 leads, were taken on July 30, August 5 and 15 and September 13. On each occasion the heart rate was approximately 60 and lead 4 was normal. On the first date, the tracings showed frequent auricular extrasystoles and notched P waves which were broader than normal, of 0.12 second's duration and 1 mm. high. T₂ was flat. On August 5 and 15, the P waves remained the same but the extrasystoles were rare and T₂ was 2 mm. high. On September 13, the P waves were of normal width and of 0.08 second's duration, although still slightly notched. Rare auricular extrasystoles were present. T₂ was the same as on the previous occasion.

The significance of these electrocardiographic changes are questionable. However, there have been reported certain electrocardiographic irregularities in the heart and also hemorrhages beneath the endocardium and in the auriculoventricular bundle in association with anaphylactic shock in animals. In dogs in dehydration shock Davis¹⁵ found a dry pericardial sac and hemorrhages in the subpericardium in the region of the coronaries and beneath the endocardium of the auricles and ventricles.

Auer and his associates¹⁶ and others¹⁷ observed that electrocardiograms in certain animals during anaphylactic reactions revealed strong and various changes of the heart's activity such as heart block, abnormal relation of P and T waves, disappearance of T and P waves, ectopic beats, large S and negative T waves, broad R and S waves and auricular fibrillation. In addition, Cripp¹⁸ found changes in the T waves like those noted

18. Cripp, L. H.: Electrocardiographic Studies of the Effect of Anaphylaxis on the Cardiac Mechanism, Arch. Int. Med. 48: 1023 (Dec.) 1931.

in coronary occlusion and suggested the possibility that the disturbance in the cardiac mechanism may be due to myocardial anoxemia. In man deLavergne and his associates¹⁹ noted a transitory Stokes-Adams syndrome with brachycardia eight days after the injection of antistreptococcus serum for erysipelas, at which time serum sickness developed. Also, Harkavy²⁰ observed certain cardiac arrhythmias and angina pectoris in 3 patients when offended by certain allergens. The relation of the changes in the electrocardiograms to the anaphylactic shock in our case is conjectured. Nevertheless, there were abnormally broad P waves and flat T_s shortly after the shock which returned to normal later.

SUMMARY

A man aged 22 had severe anaphylactic shock two hours after an injection of tetanus antitoxin. The patient was gravely ill and laboratory examinations showed hemoconcentration with a red blood count of 6,910,000. On this basis, he was given 2,000 cc. of physiologic solution of sodium chloride intravenously during a period of two hours, which resulted in dramatic improvement with recovery. The red blood cell count dropped to 5,700,000 at the end of this therapy, to 5,000,000 within six hours and to 4,610,000 within twelve hours of administration of saline solution.

It is suggested that physicians give saline solution intravenously to patients in severe anaphylactic shock along with other routine therapy.

THE VALUE OF SULFATHIAZOLE OINTMENT IN
THE TREATMENT OF PYOGENIC INFECTIONS OF THE SKIN

L. H. WINER, M.D., AND E. A. STRAKOSCH, M.D.
MINNEAPOLIS

Among the pyogenic infections of the skin, impetigo contagiosa is the most superficial and also the most common. A great deal of controversy has existed concerning the etiology of impetigo contagiosa as to whether it was caused by streptococci or by staphylococci. Recently White¹ revived the discussion of Sabouraud's claim that every case of impetigo contagiosa is of streptococcic origin. The history of this controversy is based on the work of Sabouraud,² Dohi,³ Lewandowsky,⁴ Tachau⁵ and Epstein.⁶ It is now established by the work of Engman,⁷ Dohi, Lewandowsky, Jadassohn and his school and the more recent work of Epstein that impetigo may be of either streptococcic or staphylococcic origin.

The remedies recommended for the treatment of impetigo contagiosa are legion. This fact proves that none of them is entirely satisfactory. Ammoniated mercury ointment in 1 to 5 per cent strength has probably been the most widely used remedy. Besides failing frequently in the treatment of staphylococcic impetigo, it often causes dermatitis. Drying lotions

or suspensions such as cinnabar lotion, gentian violet or silver nitrate solution are frequently used. These have the disadvantage of discoloring the skin, and silver nitrate solution often causes pain.

All these medicaments and their combinations had their place in the therapy of pyogenic infections of the skin as long as there were no specific antistreptococcus or antistaphylococcus drugs. But since it has been found that sulfanilamide is highly effective and specific against streptococcic infections and sulfathiazole against streptococcic and staphylococcic infections, there are specific chemicals which should be given first place in the attack against these infections.

The time required to cure impetigo contagiosa with the previous conventional therapy was from twelve to sixteen days, even in the hands of the most expert. Using sulfathiazole, we attempted to reduce the period of treatment.

Preliminary experimental⁸ work showed that the bacteriostatic effect of sulfathiazole was not diminished in the proper ointment bases and was most effective in a water in oil emulsion, when the base was either cholesterolated petrolatum (aquaphor) or cod liver oil ointment. Therefore we used a 5 per cent sulfathiazole in the bases mentioned and also treated a separate group of patients with sulfathiazole by mouth only, without any local applications.

In this study 60 patients with impetigo contagiosa were treated. The ages and sexes were equally distributed among the three types of treatment used in the experiment. The ages of patients varied from 8 months to 14 years. All stages of impetigo lesions were treated. The majority of patients were hospitalized for stricter observation. In a small number of patients ambulatory treatment was instituted. Twenty patients were treated with 5 per cent sulfathiazole in aquaphor. The ointment was applied two or three times a day and on small children was covered with a bandage. The time necessary for complete treatment varied from two and a half to six days (1 case only taking nine days), the average being four and four-tenths days for cure. Twenty patients were treated with 5 per cent sulfathiazole in cod liver oil ointment (cod liver oil 7.5, concentrated cod liver oil 0.12, hydrous wool fat 4 and petrolatum to make 30 parts) with an average of four and eight-tenths days for cure. Twenty patients were treated orally without any local treatment. These patients received 1.5 Gm. (3 tablets) daily under the age of 6 years and 2.5 Gm. (5 tablets) daily if over the age of 6 years. The average time required for cure was nine and one-half days.

COMMENT

From our observations it can readily be seen that the local application of sulfathiazole in ointment form definitely reduced the time necessary to treat impetigo contagiosa. At no time was there any local or general reaction to the applications. Although there were no reactions following the oral administration, the time required for cure was twice as long as with the local application, and the possibility of toxic manifestations was always present. One ounce (30 Gm.) of 5 per cent sulfathiazole ointment (1.5 Gm. of sulfathiazole) was usually sufficient for complete cure of impetigo contagiosa. The oral medication required about 14.25 Gm. of sulfathiazole per patient.

CONCLUSIONS

1. We propose the use of 5 per cent sulfathiazole ointment in a suitable base for the treatment of impetigo contagiosa.
 2. The treatment is more agreeable and cleaner than were former treatments.
 3. The time required is considerably shorter than that with previous treatment.
 4. The treatment is apparently free from dangerous sequelae.

TYPHOID IN THE LARGE CITIES OF
THE UNITED STATES IN 1940

TWENTY-NINTH ANNUAL REPORT

In anticipation of an opportunity to reassemble the number of deaths from typhoid in each of the ninety-three cities which have been included in these reports in previous years, and in order to recalculate the rates in light of the 1940 census figures, each health officer was requested to furnish the number of deaths from typhoid, both among residents and among nonresidents for each of the last eleven years, 1930 to 1940 inclusive. This procedure demonstrated how difficult is the task of obtaining for such summary figures which are altogether comparable with those secured for previous years. Many clerical errors were evident which required much correspondence and, for some cities, the rechecking of local records and original certificates. The practice regarding reallocations has varied both by time and by place, adding to the confusion. It has been our

* All typhoid deaths were stated to be in nonresidents.

† One third or more of the reported typhoid deaths were stated to be in nonresidents.

expressed intent to include all typhoid deaths, both resident and nonresident, but in spite of this declaration some health officers have entirely omitted non-resident deaths for allocations made within the state. Common denominators for purposes of comparison cannot be obtained in this way. Now that the death rates have been corrected on the basis of the 1940 census, it will probably be advisable in future reviews to build tables on the basis of resident deaths. This could not be done in the early reviews for want of a common reallocation practice. Some health officers reported cases instead of deaths, but such error became immediately apparent. Less evident was the occasional inclusion of the paratyphoids in spite of instructions to the contrary. Many health officers need pay more attention to statistics sent out from their departments, the accuracy and completeness of which are too frequently left to a casual clerk.

The estimated population on July 1 of each year, 1930 to 1939, was employed in determining rates. These

The preceding articles in this series were published in THE JOURNAL May 31, 1913, p. 1702; May 9, 1914, p. 1473; May 17, 1915, p. 1322; April 22, 1916, p. 1305; March 17, 1917, p. 845; March 16, 1918, p. 777; April 5, 1919, p. 997; March 6, 1920, p. 672; March 26, 1921, p. 860; March 25, 1922, p. 890; March 10, 1923, p. 691; Feb. 2, 1924, p. 389; March 14, 1925, p. 813; March 27, 1926, p. 948; April 9, 1927, p. 1148; May 19, 1928, p. 1624; May 18, 1929, p. 1674; May 17, 1930, p. 1574; May 9, 1931, p. 1576; April 30, 1932, p. 1550; May 13, 1933, p. 1491; May 9, 1934, p. 1677; June 8, 1935, p. 2093; June 6, 1936, p. 1983; June 19, 1937, p. 2118; July 30, 1938, p. 414; May 13, 1939, p. 1941, and May 25, 1940, p. 2103.

estimates were furnished by the Bureau of the Census. For 1940 the provisional census data were used, since the Bureau has not made population estimates for cities as of July 1, 1940.

Paratyphoid has again been excluded. In tables 1 to 8 inclusive (as well as in table 10) a special note has been made of cities in which all deaths occur among nonresidents. As far as possible this practice has been

Incomplete data.

applied to all data for the quinquennium 1936-1940. Another symbol has been used to indicate those cities in which more than one third of the reported deaths were stated to have been among nonresidents.

A comparison of deaths reported by the New England health officers shows a consistency in the annual returns made during each of the past five years and the retabulation submitted for this inquiry. There were reported in 1936 eleven deaths, in 1937 twelve, in 1938 twelve, in 1939 six, in 1940 nine, a total of fifty for the quinquennial period. Ten New England cities (Cambridge, Fall River, Hartford, Lowell, Lynn, New Bedford, New Haven, Springfield, Waterbury, Worcester) report no death from typhoid in 1940 (table 1). In 1939 there were eleven such cities. Fall River, Lynn and New Bedford record no death in four years; Cam-

Incomplete data.

bridge and Lowell extend their record to three years. Hartford, Springfield, Waterbury and Worcester report no death in two years. Of eighteen cities among the ninety-three in the United States recording no deaths from typhoid during the past two years, nine, or one half of the total, are in the New England group. Springfield reports no death among residents during the past six years. Worcester none for five years. While it was stated in the review for 1939 that Bridgeport reported

no death in six years, in light of more recent reports from the health officer Bridgeport had no death in five years (1935 to 1939). In 1940 there were three deaths in Bridgeport, all among residents. It is stated that a carrier was the source of infection for one death; the other two were traced to the eating of clams dug from polluted waters close to shore. Boston records one death among nonresidents. Of thirteen deaths during the past five years (1936-1940) only three have been among residents. For the quinquennium 1931-1935 New Haven reports but one death among residents; for the five years 1936-1940 there are six such deaths recorded. While Providence reports but seven deaths (all among residents) for the last five years, three of these deaths occurred in 1940. Likewise, of three deaths during the last quinquennium in Somerville, two are recorded for 1940. The New England cities as a whole (population 2,579,152) have lost first place among the grouped cities (table 13). The group of Middle Atlantic cities has moved from second to first place, the group of Mountain and Pacific cities occupies second place for 1940 and the New England and East North Central

deaths during these five years, only one of which was among residents. New York reports eleven deaths, all among residents. For the 1939 review the health officer reported twenty-two deaths, but in the present survey the 1939 number has been reduced to seventeen, fifteen among residents. It is stated that in the former review the deaths from paratyphoid were inadvertently included. As in other cities in the North, New York

cities tie for third place. For the quinquennial average (1936-1940) the New England group continues to hold first place.

The health officers of the Middle Atlantic cities have not proved as consistent in the reporting of typhoid deaths. On the basis of their annual returns for each of the past five years they report a total of two hundred and eighty-eight deaths, while in the present retabulation they record but two hundred and eighty-three deaths for the quinquennium 1936-1940. The first place Middle Atlantic cities (table 2) have a group rate (0.27) which is lower than that of 1939 (0.37) and 1938 (0.44). Nine cities (Buffalo, Camden, Erie, Newark, Reading, Rochester, Scranton, Utica, Yonkers) report no typhoid death in 1940. In three cities (Albany, Syracuse, Trenton) it is stated that all deaths were among nonresidents. While Utica records no death among residents during the past ten years, it is stated that one death occurred among nonresidents in each of the two years 1935 and 1939. The health officer failed to record such nonresident death in the 1939 report. Yonkers is the only city in this group to report no death for two years. Camden records no death among residents for three years, Albany for two. Buffalo reports but four typhoid deaths for the quinquennium 1936-1940, three among residents. Erie also records four

does not have an organized campaign of immunization, although such preventive treatments are advised for residents who visit camps or summer resorts where typhoid may be endemic and in families where a case exists or a carrier is discovered. In the 1939 review Paterson was included with the eight cities reporting no death. The health officer now reports one death for 1939 among nonresidents, for 1940 one death among residents. In 1939 Philadelphia reported twelve deaths, only six of which were among residents. For 1940 there are recorded twelve deaths, all but one among residents. During the last five years there were eighty-two deaths from typhoid in Philadelphia, of which seventy-three are stated to be among residents. Pittsburgh reports three deaths, all among residents. Rochester reports no death from typhoid, notwithstanding a contamination of a portion of the city water supply in December, at which time about twenty thousand inoculations were given by the health bureau. Syracuse records three deaths (all among nonresidents) during the past five years. In the group as a whole (population 13,129,185) there were thirty-six deaths in 1940, compared with forty-eight in the preceding year.

TABLE 6.—*Death Rates of Nine Cities in West North Central States from Typhoid per Hundred Thousand of Population*

† One third or more of the reported typhoid deaths were stated to be in nonresidents.

Incomplete data.

For the nine cities of the South Atlantic states (table 3) which have been included in previous reviews, the local health officers now report one hundred and eighty-two deaths instead of one hundred and eighty-four for the five years 1936-1940. The rate (0.73) is significantly lower than that of 1939 (0.93). Charlotte has been included in the group for the first time; however, for purposes of adequate comparison the figures for this city have been omitted in calculating rates for the group as a whole. Four of the ten cities (Charlotte, Jackson-

ville, Tampa, Wilmington) record no death in 1940. Charlotte and Wilmington report no death for two years. With seven deaths in 1939, Atlanta reports but two in 1940, both among nonresidents. It is stated that of three deaths in Baltimore two were among nonresidents, and of thirty-nine deaths occurring in this city

TABLE 7.—*Death Rates of Eight Cities in West South Central States from Typhoid per Hundred Thousand of Population*

† One third or more of the reported typhoid deaths were stated to be in nonresidents.

Incomplete data

during the five years 1936-1940 fourteen were thus classified. Charlotte, a newcomer among the cities of 100,000 population, records eight deaths for the quinquennium, five or which were among residents. Of five deaths in Richmond in 1940, four were among residents; of four in Washington, three were thus classified. In the nine cities (exclusive of Charlotte) there occurred twenty deaths in 1940, twenty-five in 1939, forty-eight in 1938.

To the eighteen cities (population 9,386,378) previously included in the East North Central group (table 4) has been added Gary, but again the figures for this city have been omitted in the tables for group comparison. For the eighteen cities the health officers report two hundred and forty-five deaths for the five year period 1936-1940, two more than recorded in the previous annual tabulations. It is now stated that in these eighteen cities there were sixty-nine deaths in 1936, sixty-four in 1937, thirty-four in 1938, forty-five in 1939, thirty-three in 1940. The rate for 1940 (0.35) is lower than that of 1939 (0.48) and equal to the rate for the New England cities. There are seven cities (Canton, Fort Wayne, Grand Rapids, Milwaukee, Peoria, South Bend, Youngstown) which report no

† One third or more of the reported typhoid deaths were stated to be in nonresidents.

Incomplete data

death in 1940. Fort Wayne reports no typhoid death in six years, South Bend no death in five years, Milwaukee no death in four years. In three cities (Akron, Columbus, Evansville) it is stated that all deaths were among nonresidents. Of eight deaths in Akron during the past five years, five were among nonresidents; of two in Canton, one was so classified. Chicago reports

only four deaths, all among residents. Of forty-three deaths in Chicago during the period 1936-1940, all but one were among residents. The Chicago figures do not include the deaths of Illinois residents outside Chicago and may not, therefore, be directly comparable with those of other cities. Cincinnati reports three deaths in 1940, two among residents; Cleveland six, five among residents. Of twenty-two deaths in Columbus during the quinquennium 1936-1940, twelve were among nonresidents. Of ten in Dayton, five were among nonresidents. For 1940 Dayton records six deaths, five among residents; Detroit five, all among residents. Seventeen cases of typhoid in Dayton were traced to a carrier who prepared food for a banquet held in April; later 2 other cases were traced to this same carrier. It is stated that of six deaths from typhoid in Evansville during the past five years, five were among nonresidents; of twenty-four in Indianapolis, eleven were among nonresidents; of fourteen in Toledo, six were among nonresidents.

The six cities (table 5) in the East South Central group (population 1,286,747) show a decrease in the death rate (2.09 in 1940; 2.58 in 1939). The health officers now record one hundred and sixty-one deaths for the quinquennium 1936-1940, two less than recorded

TABLE 9.—*Eighteen Cities with No Typhoid Death in 1939 and 1940*

Cambridge ††	New Bedford †
Charlotte ††	South Bend **
Duluth	Springfield
Fall River †	St. Paul
Fort Wayne *	Waterbury
Hartford	Wichita †

* No typhoid death in six years

** No typhoid death in five years.

† No typhoid death in four years

†† No typhoid death in three years

in the previous tabulations. For 1939 two cities (Louisville, Chattanooga) report no death among residents. While in 1940 there were no cities in this group, four (Louisville, Memphis, Birmingham, Nashville) report that more than one half of the deaths occurred among nonresidents (fifteen of twenty-three). Again the death rate in these urban centers is affected unfavorably by the hospitalization of cases brought in from the surrounding rural areas. Of nine deaths in Birmingham, it is stated that seven were in nonresidents. The proportion for 1940 is much higher than for the five year period (thirteen of thirty-four). Chattanooga, reporting no death in 1939, records two among residents in 1940; Knoxville two, one among residents; Louisville three, one among residents; Nashville, six, two among residents, one of whom contracted the infection outside the city limits. Reporting seventeen deaths in 1939, twelve among nonresidents, Memphis records but five deaths in 1940, and it is stated that two of these were among nonresidents. The rate for the six cities in 1940 (2.09) is slightly higher than that for the West South Central group (2.00).

The West North Central group (table 6) (population 2,716,484) shows a decrease in the death rate from 0.52 in 1939 to 0.41 in 1940. For the five years 1936-1940 the health officers record eighty-one deaths, an increase of two over the total reported in the statistics previously submitted for each of the five years. Originally reporting one death in 1938, Des Moines now records three deaths for that year. The rate for

the nine cities (0.41) approximates that (0.35) for the New England and the East North Central groups. Four cities (Des Moines, Duluth, St. Paul, Wichita) record no death in 1940. Wichita reports no death during the past four years, Duluth but one death during the quinquennium 1936-1940. Kansas City, Kan., with no death in either 1938 or 1939, reports two among residents in 1940. It is stated that in Kansas City, Mo., there were three deaths in 1940, two among residents; for the quinquennium, eighteen, eleven among residents. Minneapolis reports two deaths in 1940, both in residents; four for the five years 1936-1940, three among residents. St. Louis records three deaths, two among residents.

The cities in the West South Central group (table 7) (population 2,048,692) report a very significant reduc-

‡ Thirty-nine without Charlotte and Sacramento.

§ Forty-two without Gary.

tion in the typhoid rate (3.35 in 1939, 2.00 in 1940). The number of reported deaths dropped from sixty-eight in 1939 to forty-one in 1940. A comparison of deaths reported by the health officers in this group of cities shows a similarity between returns made during each of the five years and the retabulation submitted for this inquiry. There were reported in 1936 seventy-nine deaths, in 1937 forty-nine, in 1938 seventy-four, in 1939 sixty-eight, in 1940 forty-one, a total of three hundred and eleven for the quinquennial period. Tulsa records no death in 1940. In 1939 there was no city without a death, although three (Dallas, El Paso, Fort Worth) reported that all deaths were in nonresidents. It is stated that of nine deaths in Dallas in 1940 six were among nonresidents. Houston records six deaths with no attempt to differentiate between resident and nonresident. Of twelve deaths in New Orleans, seven were among nonresidents. San Antonio reports seven deaths, five among residents.

To the eleven cities (population 4,186,039) previously included in the Mountain and Pacific group (table 8)

has been added Sacramento, but the figures for this city have been omitted in the tables for group comparison. For the eleven cities the health officers report one hundred and twenty-three deaths for the five year

1938.....	35,578,011	237	0.72
1939.....	35,767,022	212	0.65
1940.....	35,895,638	172	0.48

Rates for Ninety-Three Cities:

1935.....	37,025,179	355	1.04
1936.....	37,241,414	366	0.98
1937.....	37,459,339	324	0.86
1938.....	37,650,155	298	0.79
1939.....	37,900,354	259	0.68
1940.....	38,060,662	190	0.50

* The following fifteen cities are omitted from this table because data for the full period are not available: Canton, Chattanooga, Dallas, Fort Wayne, Jacksonville, Knoxville, Long Beach, Miami, Oklahoma City, South Bend, Tampa, Tulsa, Utica, Wichita, Wilmington.

† Data for Fort Worth lacking.

Mountain and Pacific cities occupies second place for 1940. While in 1938 there were five cities with no death, there were but two such cities in 1939. In 1940 five cities (Denver, Portland, San Diego, Seattle, Spokane) among the original eleven record no death, and two additional cities (Oakland, Salt Lake City) report all deaths among nonresidents. Sacramento like-

wise reports no death in 1940. It is stated that in Denver there were twenty-three deaths during the four year period 1936-1939 but no death in 1940. Los Angeles records six deaths, three among residents; forty-nine for the quinquennium 1936-1940, twenty-six among residents. Sacramento records eight deaths for the five years, all among nonresidents. During the past eleven years (1930-1940) there have occurred forty-three deaths in this city, and but three of these were among residents. Patients from the delta region south of the city are brought to Sacramento hospitals for treatment. San Francisco records two deaths, one in a nonresident.

THE HONOR ROLL

The number of cities with no death from typhoid has increased to forty-one. In 1936 there were but eighteen such cities, in 1937 twenty-seven, in 1938 twenty-nine, in 1939 thirty-four. In 1939 there were fourteen cities with no typhoid death for at least two years; in 1940 there were eighteen such cities (table 9). In table 10 the cities are grouped in rank. In 1938 and again in 1939 there were three cities in third rank (rate in excess of 5.0); however, in 1940 no city falls in this rank. Less impressive is the fact that in 1940 there

TABLE 13—Total Typhoid Death Rate per Hundred Thousand of Population for Ninety-Three Cities According to Geographic Divisions

	Population	Typhoid Deaths		Typhoid Death Rates					
		1940	1939	1940	1939	1940	1939	1940	1939
..	2,579,152	9	6	0.35	0.23	0.39	0.70	1.31	
..	13,129,185	36	48	0.27	0.37	0.43	0.80	1.40	
..	2,727,985	20	25	0.73	0.93	1.14	2.70	4.50	
East North Central	9,886,378	33	45	0.35	0.48	0.53	0.75	1.29	
East South Central	1,286,747	27	31	2.09	2.58	2.54	4.31	8.31	
West North Central	2,716,484	11	14	0.41	0.52	0.60	1.24	1.61	
West South Central	2,046,692	41	68	2.00	3.45	3.09	5.56	7.32	
Mountain and Pacific	4,186,639	13	20	0.30	0.48	0.60	0.88	1.80	

† Data for South Bend for 1935-1939 are not available.
‡ Lacks data for Oklahoma City in 1936

are twelve cities with rates in excess of 2.0, while there were but ten such cities in 1939. It should be emphasized that in Trenton all deaths were among nonresidents, and in six of the remaining cities with rates in excess of 2.0 the records indicate that one third or more of deaths were among nonresidents. Nine cities in the first rank (Boston, Columbus, Akron, Oakland, Atlanta, Salt Lake City, Albany, Evansville, Syracuse) would appear (in addition to Trenton) in the honor roll were they not charged with deaths in nonresidents. The downward trend in the rates is shown in table 11.

For the quinquennium 1936-1940 the cities of the New England States have the lowest rate (0.39), followed in order by the Middle Atlantic and East North Central groups (table 13). The West North Central and Mountain and Pacific groups have the same rate (0.60). The number of deaths from 1935 to 1940 and the corresponding rates (table 12) for the seventy-eight cities and also the ninety-three cities have been corrected in light of the new figures submitted by the health officers and the census data furnished by the Bureau of the Census. For the seventy-eight cities for which data are available since 1910 there occurred one hundred and seventy-two deaths from typhoid in 1940, which is the lowest of record (two hundred and fifty-seven in 1938; two hundred and thirty-two in 1939). The rate for all cities is now just about one half of one point per hundred thousand of population. No outbreaks have been recorded. Preventive measures have been the same as reported for previous years.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS COMPLEMENTING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

AUSTIN E. SMITH, M.D., Acting Secretary

MENADIONE (pronounced mē-na-dī-one).—2-methyl-1,4-naphthoquinone— $C_{11}H_8O_2$ (M. W. 172.17). Menadione has the following structural formula:

It may be prepared by oxidizing 2-methylnaphthalene with chromic acid.

Actions and Uses.—A synthetic naphthoquinone derivative having physiologic properties of vitamin K. See the general article vitamin K, New and Nonofficial Remedies, 1941, p. 546.

Dosage.—From 1 to 2 mg. daily. The dose should not exceed 2 mg. a day and should not be continued at 2 mg. a day for a period exceeding four weeks. When the preparation is given orally, bile salts should be administered with menadione in cases of prothrombin deficiency due to bile obstruction.

Menadione occurs as a lemon yellow, crystalline powder with a faint somewhat musty odor. Under the polarizing microscope it appears as rod shaped, birefringent crystals, exhibiting oblique extinction. Menadione, especially when in solution, is sensitive to light and should be stored in the dark. It is very soluble in chloroform, soluble in acetone, benzene and ether, slightly soluble in petroleum ether and ethyl alcohol, sparingly soluble in methanol and very slightly soluble in water. The melting point of menadione is from 105 to 107°C. Grand together equal portions of menadione and phenacetin (M.P. 134-135°C) the main portion of the resulting mixture melts sharply at 95°C (eutectic melting point).

Dissolve a few crystals of menadione in 5 cc. of alcohol, add 2 cc. of an alcohol ammonia solution prepared by mixing equal parts of alcohol and concentrated ammonium hydroxide, shake and add two drops of ethyl cyanacetate a purple color develops. Add 2 cc. of six normal potassium hydroxide solution the color slowly changes from purple to green to yellow. (This color is also produced by the corresponding 2-methyl-1,4-naphthoquinone by certain other derivatives.)

Preparation.—Dissolve a few crystals of menadione in 5 cc. of alcohol, add 2 cc. of an alcohol ammonia solution prepared by mixing equal parts of alcohol and concentrated ammonium hydroxide, shake and add two drops of ethyl cyanacetate a purple color develops. Add 2 cc. of six normal potassium hydroxide solution the color slowly changes from purple to green to yellow. (This color is also produced by the corresponding 2-methyl-1,4-naphthoquinone by certain other derivatives.)

Ash 0.1 Gm. of menadione and fuse the residue with a mixture of sodium and potassium carbonates and sodium peroxide. Dissolve the cooled melt in an excess of dilute sulfuric acid, add three drops of diphenyl carbazide reagent (a 0.2 per cent solution of diphenyl carbazide in a mixture of one part of glacial acetic acid and nine parts of alcohol) and dilute to 10 cc. the color produced is not greater than that of a standard made by adding three drops of the reagent to a solution containing 0.0283 mg. of potassium dichromate in 10 cc. of water previously acidified with dilute sulfuric acid.

Dry an accurately weighed sample of menadione for eight hours over anhydrous calcium sulfate or phosphorus pentoxide; the loss in weight does not exceed 0.2 per cent. Determine the carbon and hydrogen content of a dried sample of menadione; the percentage of carbon is not less than 76.4 nor more than 76.8, the percentage of hydrogen is not less than 4.5 nor more than 4.9. The residue from the carbon hydrogen combustion or from a separate ash determination does not exceed 0.05 per cent.

Dissolve approximately 0.1 Gm. of menadione in 15 cc. of glacial acetic acid contained in a 100 cc. flask equipped with a standard ground glass joint. Add 5 cc. of water, approximately 0.2 Gm. of powdered zinc and boil under reflux for exactly ten minutes. Cool and filter through a fritted glass automatic siphon apparatus, similar to that employed for micro halogen determinations (Quantitative Organic Microanalysis by Fritz Pregl, Philadelphia, P. Blakiston's, Son & Co., Inc., 1937, page 98, fig. 32). Rinse the reaction vessel several times with small portions of glacial acetic acid and filter in the same manner. Add 15 cc. of 10 per cent sulfuric acid solution and one drop of o-phenanthroline ferrous complex indicator to the combined filtrates and titrate with 0.05 normal ceric sulfate. Each cubic centimeter of 0.05 normal ceric sulfate is equivalent to 4.305 mg. of menadione. The menadione content found is not less than 99.0 per cent nor more than 100.5 per cent.

LACTATE RINGER'S SOLUTION.—An aqueous solution containing in 1,000 cc. sodium chloride, NaCl, U. S. P. 60 Gm.; potassium chloride, KCl, N. F., 0.30 Gm.; calcium chloride, $CaCl_2 \cdot 2H_2O$, U. S. P., 0.20 Gm., and sodium lactate $NaC_2H_3O_2$, 31 Gm. The sodium lactate is prepared by neutralizing lactic acid U. S. P. with a solution of sodium hydroxide U. S. P. Certain modifications of this formula have been used, which include the addition of 0.2 Gm. of magnesium

chloride and/or 0.3 Gm. of sodium bicarbonate per thousand cubic centimeters. Lactate Ringer's solution containing either of these ingredients is labeled accordingly.

Actions and Uses.—Lactate Ringer's Solution has essentially the same use as physiologic solution of sodium chloride, and more particularly Ringer's solution. As is the case with the other salt solutions, it is approximately isotonic with body fluids and may be accompanied with various percentages of dextrose for the purpose of supplying nourishment by vein. Lactate Ringer's Solution is designed primarily for supplying the mineral needs of the body and for the purpose of maintaining or helping to maintain buffer balances.

Dosage.—Same as for Ringer's solution (N. N. R. 1941, p. 389).

Lactate Ringer's solution occurs as a clear, colorless, odorless solution, possessing a slightly saline taste. The specific gravity is from 1.006 to 1.007 at 25°C., and the μ n is not below 5.0 nor above 7.5. Twenty-five cc. of the solution concentrated to 10 cc. conforms to the U. S. P. XI test for heavy metals.

Transfer 1 cc. of lactate Ringer's solution, drop by drop, to 4 cc. of sulfuric acid contained in a test tube and keep cool by agitation in cold water. Place the test tube and contents in the steam bath for two minutes, remove the test tube and cool the contents well; add cautiously 1 cc. of a saturated aqueous guaiacol solution; a rose color develops.

Evaporate a 20 cc. portion of lactate Ringer's solution in a beaker on a steam bath until it is reduced to about 5 cc. in volume. Transfer the evaporated liquid to a suitable test tube and dilute it to 9 cc. Add 1 cc. of freshly prepared sodium cobaltic nitrite solution and mix the contents thoroughly. Treat similarly, omitting the process of evaporation, in an exactly similar test tube, a 4 cc. portion of a standard aqueous solution containing 2.0 Gm. of potassium chloride (previously dried) in 1,000 cc.; the turbidity produced by the lactate Ringer's solution at the end of fifteen minutes is less than that produced by 4 cc. of the standard solution (limit of potassium).

Transfer 5 cc. of lactate Ringer's solution to a Nessler tube; add 0.5 cc. of diluted acetic acid, 40 cc. of water and 5 cc. of ammonium oxalate solution. Dilute the solution at once to 50 cc. and mix the contents thoroughly. Treat similarly portions of a standard solution formed by dissolving 0.154 Gm. of precipitated calcium carbonate (previously dried to constant weight at 200°C.) in 10 cc. of water and 3 cc. of acetic acid, diluting the solution to 250 cc. the turbidity produced by 5 cc. of the lactate Ringer's solution at the expiration of fifteen minutes is less than that produced by 1.25 cc. and more than that produced by 1 cc. of the standard solution (limit of calcium).

Transfer 25 cc. of lactate Ringer's solution to a drying dish, evaporate to dryness on the steam bath and dry the residue to constant weight at 150°C.; the weight of residue obtained is not less than 0.245 nor more than 0.270 Gm. Evaporate a 25 cc. portion of lactate Ringer's solution to dryness, treat the residue cautiously with an excess of sulfuric acid and ignite the residue to constant weight at 750°C.; the weight of ash obtained is not less than 0.245 Gm. nor more than 0.270 Gm.

Transfer 10 cc. of lactate Ringer's solution to a 400 cc. beaker, add 50 cc. of water and 4 cc. of diluted nitric acid, dilute the solution to 200 cc., add 15 cc. of silver nitrate solution; heat the mixture to boiling and allow to cool and stand until the precipitate is granular. Filter the precipitate on a prepared Gooch crucible; wash the precipitate well with hot water; dry it to constant weight at 140-150°C. the chloride calculated from the silver chloride weighed is not less than 0.378 Gm. nor more than 0.405 Gm. per hundred cubic centimeters of lactate Ringer's solution.

Transfer 25 cc. of a potassium dichromate solution (7.6237 Gm. of $K_2Cr_2O_7$ per liter) to a 500 cc. Erlenmeyer flask, add 20 cc. of lactate Ringer's solution and 60 cc. of an aqueous solution of sulfuric acid (40% H_2SO_4). Place the flask and contents in a water bath at 70°C.; stopper the flask when the solution attains the temperature of water bath, and keep the flask and contents in the water bath for one hour. Cool the solution, add 200 cc. of water and 8 cc. of potassium iodide solution (10% KI), stopper the flask and mix the contents well, allow the solution to stand for ten minutes in a dark place, and titrate the liberated iodine with tenth normal sodium thiosulfate, using starch test solution as indicator. Make a blank test at the same time with the same quantities of reagents and correct the assay accordingly. Each cubic centimeter of dichromate solution corresponds to 0.003501 Gm. of $CH_3CHOHCOOH$. The amount of dichromate solution consumed corresponds to not less than 0.233 Gm. nor more than 0.265 Gm. of lactic acid ($CH_3CHOHCOOH$), and to not less than 0.290 Gm. nor more than 0.330 Gm. of sodium lactate ($CH_3CHOHCOONa$) per hundred cubic centimeters of lactate Ringer's solution.

Lactate Ringer's Solution in Vacoliter Container. Each hundred cubic centimeters contains sodium lactate ($NaC_2H_3O_2$) 0.31 Gm., sodium chloride U. S. P. 0.6 Gm., potassium chloride N. F. 0.03 Gm. and calcium chloride U. S. P. 0.02 Gm. Marketed in bottles (Vacoliter containers) of 500 cc. and 1,000 cc.

Prepared by Baxter Laboratories, Inc., Glenview, Ill., and Don Baxter, Inc., Glendale, Calif.

PURIFIED SOLUTION OF LIVER-10 U. S. P. UNITS PER CC.-MERRELL.—A sterile aqueous, clear, dark brown solution containing all of the fraction G of the liver extract (Cohn), preserved with 0.5 per cent of phenol. The daily parenteral administration of 0.1 cc. has been found to produce the standard reticulocyte response defined as 1 U. S. P. unit (injectable) when assayed in cases of pernicious anemia as required by the Council.

Actions and Uses.—Purified Solution of Liver-Merrell is recommended for intramuscular use in the treatment of pernicious anemia. See the general article Liver and Stomach Preparations (New and Nonofficial Remedies, 1941, p. 328).

Dosage.—For the average case in relapse, 10 U. S. P. injectable units (1 cc.) may be injected as the initial dose. Subsequent doses from 5 to 10 U. S. P. injectable units (0.5 to 10 cc.) may be given weekly until the blood picture has

returned to normal. The maintenance dose should be not less than 1 U. S. P. injectable unit (0.1 cc.) daily and should be adjusted to the needs of the individual patient depending on the degree of complications. It may be administered at weekly or longer intervals in equivalent cumulative doses (15 U. S. P. injectable units twice a month).

Distributed by Wm. S. Merrell Co., Cincinnati
Vials Purified Solution of Liver-Merrell (10 U. S. P. injectable units per cc.) 5 cc.

Purified Solution of Liver Merrell, 10 units per cubic centimeter, is prepared as follows: Fresh edible liver is extracted with water at 170°F. for thirty minutes and filtered. The filtrate is concentrated in vacuo and extracted with 70 per cent alcohol; the alcoholic extracts are concentrated in vacuo and precipitated with ammonium sulfate. The precipitate is further purified by alcoholic fractionation, the alcohol removed and the extract made up to volume so that each cubic centimeter contains the extract from 100 Gm. of fresh liver. Five tenths per cent phenol is used as a preservative.

PURIFIED SOLUTION OF LIVER-5 U. S. P. UNITS PER CC.-MERRELL.—A sterile aqueous, clear, dark brown solution containing all of the fraction G of the liver extract (Cohn), preserved with 0.5 per cent of phenol. The daily parenteral administration of 0.2 cc. has been found to produce the standard reticulocyte response defined as 1 U. S. P. unit (injectable) when assayed in cases of pernicious anemia as required by the Council.

Actions and Uses.—Purified Solution of Liver-Merrell is recommended for intramuscular use in the treatment of pernicious anemia. See the general article Liver and Stomach Preparations (New and Nonofficial Remedies, 1941, p. 328).

Dosage.—For the average case in relapse, 10 U. S. P. injectable units (2 cc.) may be injected as the initial dose. Subsequent doses from 5 to 10 U. S. P. injectable units (1 to 2 cc.) may be given weekly until the blood picture has returned to normal. The maintenance dose should be not less than 1 U. S. P. injectable unit (0.2 cc.) daily and should be adjusted to the needs of the individual patient depending on the degree of complications. It may be administered at weekly or longer intervals in equivalent cumulative doses (15 U. S. P. injectable units twice a month).

Distributed by Wm. S. Merrell Co., Cincinnati
Vials Purified Solution of Liver Merrell (5 U. S. P. injectable units per cc.) 10 cc.

Purified Solution of Liver Merrell, 5 units per cubic centimeter, is prepared as follows: Fresh edible liver is extracted with water at 170°F. for thirty minutes and filtered. The filtrate is concentrated in vacuo and extracted with 70 per cent alcohol; the alcoholic extracts are concentrated in vacuo and precipitated with ammonium sulfate. The precipitate is further purified by alcoholic fractionation, the alcohol removed and the extract made up to volume so that each cubic centimeter contains the extract from 50 Gm. of fresh liver. Five tenths per cent phenol is used as a preservative.

DEXTROSE (See New and Nonofficial Remedies, 1941, p. 179).

Baxter Laboratories, Inc., Glenview, Ill., and Don Baxter, Inc., Glendale, Calif. (American Hospital Supply Corporation, Chicago, eastern distributor).

Dextrose 5% W/V in Ringer's Solution in Vacoliter Container: Each hundred cubic centimeters contains dextrose U. S. P. 5 Gm., sodium chloride U. S. P. 0.7 Gm., potassium chloride N. F. 0.03 Gm. and calcium chloride U. S. P. 0.025 Gm. Supplied in bottles (Vacoliter containers) of 500 cc. and 1,000 cc.

Dextrose 10% W/V in Ringer's Solution in Vacoliter Container: Each hundred cubic centimeters contains dextrose U. S. P. 10 Gm., sodium chloride U. S. P. 0.7 Gm., potassium chloride N. F. 0.03 Gm. and calcium chloride U. S. P. 0.025 Gm. Supplied in bottles (Vacoliter containers) of 500 cc. and 1,000 cc.

Baxter Laboratories, Inc., Glenview, Ill. (American Hospital Supply Corporation, Chicago, eastern distributor).

Dextrose 5% W/V in Lactate Ringer's Solution in Vacoliter Container: Each hundred cubic centimeters contains dextrose U. S. P. 5 Gm., sodium lactate ($NaC_2H_3O_2$) 0.31 Gm., sodium chloride U. S. P. 0.6 Gm., potassium chloride N. F. 0.03 Gm. and calcium chloride U. S. P. 0.02 Gm. Marketed in bottles (Vacoliter containers) of 500 cc. and 1,000 cc.

Dextrose 10% W/V in Lactate Ringer's Solution in Vacoliter Container: Each hundred cubic centimeters contains dextrose U. S. P. 10 Gm., sodium lactate ($NaC_2H_3O_2$) 0.31 Gm., sodium chloride U. S. P. 0.6 Gm., potassium chloride N. F. 0.03 Gm. and calcium chloride U. S. P. 0.02 Gm. Marketed in bottles (Vacoliter containers) of 500 cc. and 1,000 cc.

SOLUTION OF EPINEPHRINE HYDROCHLORIDE-U. S. P. (See New and Nonofficial Remedies, 1941, p. 254).

SOLUTION EPINEPHRINE HYDROCHLORIDE 1:1,000-ENDO.—A brand of solution epinephrine hydrochloride-U. S. P. containing chlorobutanol 0.5 per cent and sodium bisulfate not more than 0.1 per cent, as preservative, in physiologic solution of sodium chloride.

Prepared by Endo Products Inc., Richmond Hill, N. Y.
Solution Epinephrine Hydrochloride, 1:1,000 Endo, 30 cc. vial: Marketed in vacuum stoppered vials for parenteral administration and in cork stoppered vials for topical administration.

Solution Epinephrine Hydrochloride, 1:1,000 Endo, 1 cc. amp.

SATURDAY, JANUARY 17, 1942

PROVISION OF MEDICAL OFFICERS FOR MILITARY SERVICES

The questionnaires published in recent issues of *The Journal* elicited many thousands of replies. The requirements of military necessity do not permit stating the exact numbers of names which have been furnished to the Surgeon General at this time or the number who will be requested to come immediately into the service. Appreciation is tendered particularly to the secretaries of state medical societies and to the editors of state medical journals, who gave complete cooperation in circularization of the appeal to the medical profession.

Under *Medical Preparedness* in this issue of *The Journal* appears a statement from the Procurement and Assignment Service regarding the present status of needs of the armed services and other federal agencies, and regarding also actions recently taken by the Board of the Procurement and Assignment Service for Physicians, Dentists and Veterinarians in relation to some questions that have been raised. Every physician in the United States is likely to find before the war is over that special need for his services in some capacity has arisen. The number of physicians to be called into the armed services clearly is sufficiently great to dislocate much of the present status of medical practice. One needs only to point out that the expansion of the Army by another million men would require at least seven thousand additional physicians. An army of four million men would necessitate a total of about thirty-two thousand physicians taken from civilian practice. Moreover, the call is primarily for men under 36 years of age and at most under 45 years of age. On January 15 every medical reserve officer in a governmental department or agency and physically fit was notified that he would be considered available for active duty.

The whole purpose of the Procurement and Assignment Service for Physicians, Dentists and Veterinarians

is to provide for the needs of the armed forces with the minimum amount of dislocation of medical service to civilian needs, including public health agencies, industrial plants and medical education. Another primary purpose is to place, as far as possible, men with special qualifications in duties for which they are particularly fitted. These purposes can be accomplished with the complete cooperation of the medical profession. Should the war be prolonged, however, from two to three years the majority of physicians under 45 years of age who are physically fit will be engaged in the military services. Those who are not physically fit to meet the standards of the Army and the Navy will unquestionably be called on for additional services beyond the practices in which they are now engaged. The needs of civilian defense, industry and public health must be met. The Procurement and Assignment Service plans to give to every physician who enrolls with that service for assignment a certificate and a numbered button to indicate that he has made himself available to the nation in this time of emergency. The medical profession can be depended on to do its utmost. Let us not fail!

SPEEDING PRODUCTION OF PHYSICIANS

Already several medical schools have announced the readjustment of their curriculums so that the sessions will be practically continuous, in order to speed production of physicians and possibly also to increase the total number of physicians graduating each year. For more than twenty years the medical schools of this country have accepted each year slightly over six thousand students. Each year a certain percentage of these students have been dropped from the schools because of poor scholarship or for other reasons; the total number of medical graduates has been approximately five thousand three hundred annually. More than twelve thousand graduates of colleges and some with just two or three years of college education apply each year for entrance into the medical schools. Selections are made with the greatest of care. Since a considerable percentage of those selected are still found to be unable to complete the course because of poor scholarship, many educators have been convinced that six thousand students represent all of the really well qualified candidates for the medical profession that become available. Thus the proposal to increase greatly the number of young men admitted to medical school or to modify the curriculum has caused great concern to leaders in medical education and medical practice. For more than thirty years the struggle to develop a high standard of medical education and to maintain that standard has been a difficult but a successful one. Without a doubt the standards of medical education in the United States are superior to those anywhere

else in the world. The quality of medical service available to the public of the United States is as good as can be found anywhere else in the world. No doubt, distribution of practice may be improved—but that is another question!

The Council on Medical Education and Hospitals of the American Medical Association is, of course, anxious to do everything that can be done to provide a sufficient number of well qualified physicians for the armed forces and for the civilian needs. Nevertheless, familiarity with the physical assets and faculties of the medical schools of the United States causes the Council to have some doubts as to whether every medical school in the country is capable of undertaking an increase in the number of students admitted and of embarking on a continuous session of study and yet maintaining the standards of medical education that the Council has set forth as a minimum. These considerations must not be overlooked. Perhaps the impulsive action taken by the Committee on Medical Preparedness of the Association of American Medical Colleges, presumably as a defense measure, was somewhat too sudden. Perhaps the Health and Medical Committee should have given consideration to this matter. Indeed, there does not yet appear to have been issued from the Health and Medical Committee or any other official agency any statement to the effect that it has given approval.

As one leading educator said, "I feel that those responsible have not thought the proposal through." Here are some of the difficulties that do not yet seem to have been solved:

1. If the young men entering medical schools in June 1942 complete the course in thirty-six consecutive months they will be graduated in June 1945 instead of June 1946. However, they will still require a year of internship, thus making them unavailable for military service until the end of June 1946. As an emergency measure the immediate gain is slight.

2. Many students have been accustomed to utilize the summer vacations to earn funds to finance their medical course. If summer vacations are to be eliminated, these students either will have to be financed from some other source or discontinue their medical education.

3. Many medical students enrolled in the Reserve Officers Training Corps are under obligation to serve a period of training in the field. This must be discontinued if the medical curriculum is to occupy thirty-six consecutive months.

4. If some students follow the thirty-six consecutive month concept and others try to continue the original plan of four years of nine months each, the physical facilities and the technical and teaching staffs will have to be greatly increased or devote far more time than is now given.

5. Unless colleges, universities and hospitals have their curriculums suitably integrated with the curriculums of the medical schools, the students will lose from three to six months spent waiting for entrance into medical courses or to internships in hospitals somewhere along the line.

These are a few of the problems that have been raised and for which solutions do not yet appear to be fully available. Most important, however, is the question of maintaining accepted medical standards. If more students are admitted and a larger percentage fails, little useful purpose will have been achieved. If examinations are abolished, if pressure on a faculty makes it pass unqualified men, if standards of study required for graduation are lowered so that a larger number of students each year receive the medical degree, the ultimate effect will be serious both on the army medical services and on service to the people. Such lowering of professional standards cannot be in the best interests of the nation.

Current Comment

PHYSICAL OR PSYCHIC ALLERGY

A woman aged 31 developed giant hives over her legs after swimming. When she washed with cold water, scattered hives would form. Previously she had not had asthma, hay fever or eczema. Intracutaneous tests with a routine group of inhalants and foods were negative. Dermographism was absent. However, when tested with a standard cold stimulus (cracked ice in a test tube) the patient developed well formed wheals without pseudopods after one minute's application. This sudden change in the patient's reactivity to cold coincided, according to Abramson,¹ with a recent mental conflict. The patient was depressed by the news of war fatalities involving intimate friends. The day previous to the occurrence of hives, while swimming, she had felt that she wanted to drown. On one occasion, despite a severe reaction after swimming, there were no symptoms suggestive of a histamine-like reaction. Abramson points out that the absence of pseudopods and the formation of giant hives without constitutional symptoms suggests that the phenomenon cannot be accounted for by the liberation of a histamine-like substance. The main feature of the case was the suddenness of the onset immediately after a relatively short period of mental conflict which endangered the patient's life. With the change in the patient's point of view the whealing response to cold has disappeared. The case represents a spontaneous recovery from a whealing response to cold without the use of histamine or any other desensitizing agent. While the report concerns but a single instance, so that conclusions can hardly be warranted, the record is suggestive.

ROENTGEN THERAPY OF GAS BACILLUS INFECTION

Cantril¹ has recently deplored the lack of appreciation by physicians of the value of treatment of gas bacillus infection with the roentgen ray. Five cases are reported as successfully treated. "Débridement or other surgical procedures in the acute phase of an already established gas bacillus infection," he writes, "is not indicated when roentgen therapy is available. Any manipulation or operative procedure is best done after the acute gas infection has subsided or at least until adequate trial of roentgen therapy has been given. The technic of roentgen irradiation requires the use of large fields and the irradiation of far more of the body than the locally involved area. From 500 to 100 roentgens per field should be given two to three times daily for a period of three to five days." Four of his patients received adequate amounts of gas bacillus antitoxin; 1 patient received, in addition, multiple blood transfusions, and another patient had a limb amputated. In view of the generally accepted efficacy of the serum in the treatment of gas bacillus infection, it would be difficult to say whether the recovery of 4 patients was due to roentgen therapy or to serum therapy. The same criticism may be applied to the report of Faust,² who treated 5 patients with serum and the roentgen ray. The most enthusiastic proponent of roentgen therapy in gas bacillus infection is Kelly,³ who reported 143 cases, some treated personally and others based on data from questionnaires returned by a hundred physicians scattered throughout the United States and Canada. Kelly and his co-workers were enthusiastic over the results of roentgen treatment of gas gangrene, saying that the results far surpassed those obtained with serums, débridement and amputations. They were inclined to regard roentgen therapy in gas gangrene as a specific and stated that, if it is employed during the first twenty-four hours, recovery will occur in all cases. Nevertheless Cubbins, Callahan and Scuderi⁴ state "We are positive that the x-ray treatment of gas bacillus infection has little, if any, value. In 8 cases of proved gas infection that were treated with x-ray without surgery or antitoxin, there were 8 deaths. X-ray will destroy tissues and no amount of it will serve to disturb the growth and reproduction of gas bacillus when it is applied to cultures. We can see no reason for even considering x-ray in the treatment of these cases." Attempts to reproduce the clinical effects in animal experiments thus far have failed. Caldwell⁵ induced gas bacillus infection in guinea pigs and treated them one to three hours after inoculation with from 100 to

200 roentgens. Of the 10 animals thus treated, 7 died after eight to eighteen hours. Apparently the determination of the specificity or efficacy of roentgen therapy in gas bacillus infection must await more rigidly controlled clinical investigations in an adequate number of cases.

FINLAY INSTITUTE OF THE AMERICAS

On January 6 in the Medical School of the University of Havana an agreement was reached for the establishment of an organization known as the Finlay Institute of the Americas to foster research and education in the field of tropical disease and to provide for an increased interchange of medical students and teachers among scientific medical institutions in all the American nations. Mr. Basil O'Connor, at present president of the National Foundation for Infantile Paralysis, accepted the presidency of the executive council. Dr. James E. Paullin, president-elect of the American College of Surgeons, was appointed chairman of the Scientific Advisory Committee for the United States. Other members appointed to the executive council included Drs. Thomas Mackie, president of the American Society of Tropical Disease; Dr. Morris Fishbein, editor of *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*; Dr. Edgar Mayer, associate professor of medicine in Cornell University and also in the University of Havana; Dr. Enrique Saladrigas, director of the Finlay Institute of the University of Havana; Dr. Rafael Menocal, professor of surgery in the University of Havana, and Dr. Felix Hurtado, assistant minister of public health of Cuba. Executive offices will be established both in Havana and in New York. The Cuban government agreed to provide \$20,000 annually for maintenance of the organization. Substantial contributions were made by several American industrialists and philanthropists. In the course of the negotiations for the establishment of the Finlay Institute of the Americas Mr. O'Connor presented to President Batista of Cuba and to the minister of public health, Dr. Marruz, messages from President Roosevelt and Vice President Henry Wallace, indicating their approval of the project to foster more intense cooperation between scientific institutions of the Latin American countries. Mr. Donald Nelson, who accompanied the party to Cuba, also conferred with President Batista. The University of Havana and the medical school of the university, during the course of the negotiations, provided receptions by their faculties, and addresses were made by the American visitors and also by leading Cuban officials. Representatives of the Cuban Federation of Medicine also presented to the American delegation an offer of complete cooperation in the campaign for medical service in the war. The order of Carlos Finlay was conferred on the American visitors by President Batista. A constitution and by-laws are being prepared for the conduct of the new institute, which should serve a most useful purpose in fostering scientific interchange and good will among the medical professions of all the Latin American countries.

MEDICAL PREPAREDNESS

In this section of The Journal each week will appear official notices by the Committee on Medical Preparedness of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medical preparedness, and such other information and announcements as will be useful to the medical profession.

PROCUREMENT AND ASSIGNMENT SERVICE FOR PHYSICIANS, DENTISTS AND VETERINARIANS

PROVISION OF MEDICAL OFFICERS FOR MILITARY SERVICES

At the time of the Pearl Harbor incident, Dec. 7, 1941, the Army was short approximately fifteen hundred physicians to bring all existing installations up to war strength. Requisition was made on the Procurement and Assignment Service immediately to secure such physicians under the age of 36. The number of physicians in the service was adequate to meet all professional demands in the care of patients but was not sufficient to provide physicians for all organizations on a war strength basis. Therefore the Procurement and Assignment Service on December 18 authorized the publication of application blanks for enrolment with a view to meeting the immediate needs of the Army. These blanks have been circulated by THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION and by many state organizations. Some confusion has arisen in that many physicians interpreted the enrolment blank as another call for every physician in the United States to register. Actually, only those ready to volunteer for immediate service were wanted and only the applications of those capable of meeting specified qualifications are being forwarded.

The continued registration of all MEN UNDER 36 WHO ARE IMMEDIATELY AVAILABLE for military duty in the Army or the Navy will suffice to meet the immediate needs of the military services, at least until completion of the roster system now being established in the office of the Procurement and Assignment Service.

Within sixty days the Procurement and Assignment Service expects to publish the physical requirements for service with every military, governmental, industrial and civil agency utilizing the services of physicians, dentists and veterinarians. Each physician, dentist or veterinarian will be asked to make a self analysis of his physical condition, so that he may himself determine with which of the agencies he is physically qualified to serve. Shortly thereafter the Procurement and Assignment Service expects to mail a new questionnaire and enrolment form. Each professionally qualified person will be asked to state, first, that he will volunteer his services in the interest of the national emergency; second, to state his first, second, third and

fourth choice of the agencies which he will be willing to serve for the duration of the war. A list will be furnished of every military, governmental, industrial and civil agency requiring the services of physicians, dentists or veterinarians.

On self analysis of his physical condition, each man will be thus able to determine whether his physical fitness qualifies him for duty with the requisitioning agencies. On receipt of the enrolment form the Procurement and Assignment Service will issue a certificate of enrolment and a numbered button which will certify that the recipient has offered his services in the interests of the national defense. Thus, those who remain at home in an essential capacity will derive the satisfaction of knowing that they have offered their utmost to the national emergency and that this offer has been formally recognized by the Procurement and Assignment Service.

SAM F. SEELEY, Executive Officer

MORRIS FISHBEIN, Chairman Committee on Information.

Procurement and Assignment Service.

PHYSICIANS NEEDED FOR RED CROSS BLOOD PROCUREMENT PROGRAM

The expansion of the blood procurement program under the auspices of the American Red Cross will require the services of physicians in a full-time capacity. In the near future there will be published in this section a statement as to the number of physicians required, the age group, the professional qualifications and a list of those to whom they will be asked to make direct application. The physicians wanted for this service will be preferably those over 45 years of age or, if under 45 years of age, not physically fit for the armed services.

OFFICE OF CIVILIAN DEFENSE REQUISITION FOR DEFENSE AREA DIRECTORS FILLED

The requisition which was published in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION for Dec. 13, 1941 for two men between the ages of 45 and 60 for duty as reserve officers of the United States Public Health Service as defense area directors for the Office of Civilian Defense has been filled. Several hundred applications were received in the office of the Procurement and Assignment Service and were forwarded to the Office of Civilian Defense.

CANCEL DEFERMENTS OF RESERVE OFFICERS WHO ARE FEDERAL EMPLOYEES

The Secretary of War issued the following instructions, January 5:

1. In September 1940 the War Department promulgated a policy permitting Reserve officers who were employed in key civilian positions in the various governmental departments and agencies to be granted unlimited deferments from military duty by being transferred to the War Department Reserve Pool. Because of the present state of war, these deferments will be canceled, effective Jan. 15, 1942, and all affected Reserve officers will be considered available for active duty after notice of relief from the War Department Reserve Pool by this office.

2. Requests for limited deferments should be submitted in triplicate, addressed to the Adjutant General, Washington, D. C., and signed by the responsible head of the department or agency making the request. Such requests will receive favorable con-

sideration, to the extent that military necessity permits, in exceptional cases only. No general or permanent deferments will be authorized. Requests for deferment submitted after active duty orders have been issued cannot be considered.

3. The following information should be furnished with each request for deferment: (a) Name of the officer in full (initials should not be used). (b) Rank and branch in which commissioned. (c) Home address as last reported to the War Department. (d) Date of birth. (e) Title of present position (governmental payroll designation). (f) Salary or wages. (g) Civil service rating, if any. (h) Length of time in present position. (i) Total time in the employ of the present department or agency. (j) Total time in federal employ. (k) Detailed description of present duties. Include information as to the availability of a replacement or the time required to train one. (l) Length of deferment desired (until—give date).

By order of the Secretary of War:

E. S. ADAMS,
Major General,
the Adjutant General.

HARVARD'S BASE HOSPITAL ORDERED ABROAD

Orders for the mobilization of Base Hospital Unit No. 5 have been received, it was announced by Harvard University, January 5. While preliminary orders advising personnel that they would be shortly called were received on December 24, the latest orders provide for report to an eastern seaboard camp in the near future and their departure from the country shortly thereafter. At the request of the university, Dr. Elliott C. Cutler, director, will not proceed with the unit. Dr. Thomas H. Lanman, chief of the surgical service of the unit, will serve as acting director. The request for Dr. Cutler's release was made because of the need of his services in Boston.

Base Hospital No. 5, organized by Harvard Medical School, is a continuation of Base Hospital No. 5 which operated in France during the last war. Associates of the following Boston hospitals and departments of Harvard University are included among the officer personnel: Boston City Hospital, Beth Israel Hospital, Boston Lying-in Hospital, Children's Hospital, Deaconess Hospital, Eye and Ear Infirmary, Faulkner Hospital, Hygiene Department of Harvard University, Harvard Dental School, Harvard School of Dental Medicine, Harvard Medical School, Massachusetts General Hospital and Peter Bent Brigham Hospital.

Among the nursing personnel will be forty-four nurses from the Boston area.

The officer personnel of the hospital at present is as follows:
Unit director: Lieut. Col. Thomas H. Lanman.

Surgical service: Lieut. Col. Thomas H. Lanman, chief; Major Augustus Thorndike, assistant chief; Majors Edwin F. Cave, J. E. Dunphy, Carlyle G. Flake, John H. Harrison, Robert Zollinger; Capts. Thomas W. Botsford, Thomas Cavanaugh, Stanley O. Hoerr, Lee G. Kendall, John L. Newell, T. B. Quigley, Charles P. Sheldon, Fiorindo A. Simeone, Dean W. Tanner, Richard Warren; 1st Lieuts. Chilton Crane, Charles L. Dimmler Jr., Robert G. Snow, Robert R. White.

Medical service: Lieut. Col. Theodore L. Badger, chief; Major Eugene O. Eppinger, assistant chief; Majors Harold F. Corson, J. E. Greene, Stanley Kimball, Harold Levine, Charles May, Henry N. Pratt; Capts. Arthur Baldwin, Richard V. Ebert, Charles P. Emerson, Joseph Frothingham, Paul Kunkel, Jack D. Myers, Carey M. Peters, Gordon A. Sanders, Roy L. Swank; 1st Lieuts. Samuel Asper, Henry H. Brewster, Joseph H. Burchenal, Sibley W. Hoobler.

Laboratory: Major Dale Friend, Capt. Joseph H. Bragdon, 1st Lieut. Richard Ford.

X-ray: Major Magnus I. Smedal, Capt. Donald P. Ham, 1st Lieut. Ralph C. Moore.

Headquarters: Capt. John J. Kneisel.

Registrar: Majors Beach Hazzard, Norman Vaughan, Quartermaster Corps; 1st Lieut. Frederick P. Ross.

Mess: Major George F. Wilkins.

Dental Corps: Major Moses S. Strock; Capts. Henry J. Carney, Harry Stone, George Sullivan; 1st Lieuts. Maurice Dinnerman, Gerald L. O'Neill, Maxwell Periman.

BLOOD BANKS FOR CIVILIAN DEFENSE

The Medical Advisory Board of the Office of Civilian Defense held a joint meeting with the Regional Medical Officers at the national headquarters in Washington, Dec. 8-9, 1941. Mayor La Guardia, U. S. Director of Civilian Defense, addressed the group briefly, urging action on two counts: organization of emergency medical field units and designation of field casualty stations in the target areas on both coasts.

The medical defense officials decided that it is necessary that blood banks, as well as collecting stations for plasma and serum, similar to those developed by the American Red Cross for the Army and Navy, be established for civilian use. It was pointed out that a supply of whole blood and of plasma and serum for use among civilians is essential, as the armed forces will not be able to release any of their supply under conditions of actual warfare.

Dr. Wallace D. Hunt, medical officer for the Ninth Civilian Defense Region with headquarters in San Francisco, reported that the important cities of the West Coast, especially those in California, had well developed disaster services and that these were being rapidly integrated into the comprehensive civilian defense program.

Members of the Medical Advisory Board who attended the meeting were Drs. George Bachr, New York, chairman of the board and chief medical officer of the Office of Civilian Defense; Robin C. Buerki, Philadelphia; Elliott C. Cutler, Boston; Oliver B. Kiel, Wichita Falls, Texas; Albert McCown, Washington, and Huntington Williams, Baltimore. Dr. Fred Rankin, Lexington, Ky., was unable to be present.

Regional medical officers present, in addition to Dr. Hunt, were Drs. Allan M. Butler, Boston, first civilian defense region; H. Van Zile Hyde, New York, second region; W. Ross Cameron, Baltimore, third region; Judson D. Dowling, Atlanta, Ga., newly appointed to the fourth region; William S. Keller, Columbus, Ohio, fifth region, and Witten B. Russ, San Antonio, Texas, eighth region.

Others present included Miss Mary Beard, director of nursing service, American Red Cross; Dr. James A. Crabtree, executive secretary, Health and Medical Committee of the Office of Defense Health and Welfare Services; Dr. Thomas Parran, Surgeon General, and Dr. Erval R. Coffey of the U. S. Public Health Service and Dr. Martha Eliot of the U. S. Children's Bureau.

SANITARY ENGINEERING IN CIVILIAN DEFENSE

Ralph E. Tarbett, senior sanitary engineer, U. S. Public Health Service, is chief sanitary engineer of the medical division of the Office of Civilian Defense. Mr. Gordon E. McCallum, sanitary engineer, U. S. Public Health Service, has been commissioned in the Public Health Service Reserve and assigned to the third civilian defense region (Pennsylvania, Maryland, District of Columbia and Virginia) plus West Virginia and Ohio. Mr. McCallum is stationed in Washington. Mr. John H.

Brewster, Troy, N. Y., at one time with the Indiana and later with the New York state health department, has also been commissioned in the Public Health Service and assigned to the first and second defense regions.

The National Technological Civil Protection Committee, an advisory group to the War Department, has agreed to serve in the same capacity to the Medical Division of OCD in matters of public health engineering. Mr. Walter Binger of New York, representing the American Society of Civil Engineers, is chairman of this committee. Other members represent other national engineering and related organizations.

The sanitary engineering section will work through state defense councils with state health departments in planning to meet the problems that may arise from belligerent action. Of these, the maintenance of a continuous supply of safe water is of first importance.

CIVILIAN DEFENSE IN THE DISTRICT OF COLUMBIA

The plans of the third defense area, comprising the District of Columbia, Maryland, Virginia and Pennsylvania, were discussed on December 16 at a conference in Washington called by Dr. W. R. Cameron, Hagerstown, Md., medical officer of the third defense area, and attended by Drs. W. P. Dodds of Harrisburg, Pa.; C. R. Edwards and R. H. Riley, both of Baltimore; William Grossmann and I. C. Riggin, both of Richmond, Va.; George C. Ruhland and John Reed of the District of Columbia, and army and navy officers. The Maryland, the Virginia and the District of Columbia medical officials agreed on plans for two five hundred bed evacuation hospitals in Bethesda, Md., and the Arlington, Va., area to be used for the less seriously injured in order to make beds available in the city hospitals in case of need of emergency treatment of numerous casualties.

Plans to mobilize the fifteen hundred doctors in the Washington area for emergency civilian defense medical work were discussed before the Medical Society of the District of Columbia, December 10, by Dr. Oscar B. Hunter, assistant chief civilian defense medical officer. Physicians will be assigned to the various hospitals from which they will conduct emergency civilian defense work. Among the medical officers listed as assistant chief medical officers are William E. Clark (voluntary agencies), W. R. Morris (casualty stations), Philip O. Pelland (transportation), Paul F. Dickens (government agencies), James A. O'Keefe (organization assistant), Phillip T. Johnson (organization assistant for Negro medical group), William B. King (liaison officer for metropolitan Virginia), Reed N. Calver (liaison officer for metropolitan Maryland), O. K. Fike (hospital mobilization) and Oscar B. Hunter (personnel).

LECTURES ON FIRST AID

The Medical Society of the County of New York, the New York Academy of Medicine and the chief of Medical Emergency Service for Manhattan sponsored a series of four lectures and demonstrations on first aid given to New York physicians the early part of January at the New York Academy of Medicine building, 2 East 103d Street. Dr. George Baehr, director of the medical division, National Office of Civilian Defense, Washington, D. C., discussed the organization of medical emergency service in New York; Capt. Charles D. Scully of the New York chapter of the American Red Cross discussed principles and management of first aid; Dr. Robert H. Kennedy, director of surgery at Beekman Hospital and chairman of the National Fracture Committee, the emergency care and transportation of persons with fractures; Dr. Frederick W. Bancroft, New York, the emergency care of abdominal, head and chest injuries and burns, and Dr. Lawrence M. Thompson the emergency care of wounds, hemorrhage and shock. The lectures were based on the course in advanced first aid prepared by the American Red Cross and the Office of Civilian Defense and were announced by Dr. Condict W. Cutler Jr., borough chief of emergency medical service. Dr. Baehr said that emergency medical field units had been organized and drilled in eighty hospitals in the metropolitan area and that the medical personnel of this emer-

gency medical service now comprised two thousand, one hundred and forty-eight physicians and nurses. These field units are subdivided into emergency squads, and certain squads are on emergency call day and night.

MEETING OF HOSPITAL PROTECTION COMMITTEE

The Subcommittee on Air Raid Protection of Hospitals of the Medical Advisory Board, Office of Civilian Defense, met in New York, Dec. 6, 1941, to complete a report, which will shortly be published by the Office of Civilian Defense as an official bulletin. Present at the meeting were Drs. George Baehr, chairman of the Medical Advisory Board; Robin C. Buerki, Philadelphia, a member of the Medical Advisory Board and chairman of the subcommittee; Asabel J. Hockett, New Orleans, Joseph Turner, New York, and Anthony J. J. Rourke, New Orleans, members of the committee; Ward L. Mould of the Washington headquarters; John J. Bourke, Albany, N. Y., research director, New York State Health Preparedness Commission; H. Van Zile Hyde, New York, regional medical officer for the second region, and Dr. James M. Mackintosh, professor of public health, University of Glasgow, Scotland, and former chief medical officer of the Scottish Ministry of Health, who has been acting as a consultant to the subcommittee.

ARMY SCHOOLS FOR COOKS AND BAKERS

There are now about fifty Army bakers' and cooks' schools throughout the nine corps areas, the Quartermaster Corps announces, and they are turning out bakers, cooks, mess sergeants and mess officers with clocklike regularity. At a typical school, 5,648 students were graduated during the past year, compared with an average of 175 a year that had been graduated since the World War.

In general, courses have been revised to provide shorter and more intensive training. The mess officers' course has been cut to one month, and officer students spend forty hours in actual classroom work. Mess sergeants also complete their training in one month, but all the students in this course are already graduate cooks. Student bakers and cooks are put through a two months course.

EMERGENCY MEDICAL EQUIPMENT

The Medical and Surgical Relief Committee of America, 420 Lexington Avenue, New York, sent eight emergency medical field sets, January 2, to medical directors of the Second Civilian Defense Region, comprising New York, New Jersey and Delaware. Each set consists of two portable cases equipped with instruments and supplies, which will be placed in hospitals and first aid posts in various locations, whence they can be readily transported to potential points of disaster. Plans are being made by the committee for a nationwide campaign to provide quantities of these sets in each of the nine civilian defense regions set up by the Office of Civilian Defense; it is estimated that seven hundred and twenty-four sets will be required to meet the needs of New York City alone.

BRYN MAWR NAVAL HOSPITAL PHYSICIANS ORDERED TO DUTY

Eighteen physicians of the staff of Naval Base Hospital No. 33, organized at Bryn Mawr Hospital, Pa., were ordered to report for active duty at the Navy Yard, Washington, D. C., January 5. This unit is expected to take over a naval base hospital at some undesignated location. The remainder of the medical complement and enlisted personnel will be made up in the field. The head of the unit is Dr. George Wagoner of Haverford, chief of orthopedics at Bryn Mawr Hospital; the medical chief is Dr. John K. Durkin and the surgical chief Dr. Frederick R. Robbins, both of Bryn Mawr. This is the first of five military hospitals in the Philadelphia area to be ordered to active duty.

ORGANIZATION SECTION

MEDICAL RELATIONSHIPS OF THE AMERICAN NATIONS

LOIS STICE

CHICAGO

The United States Department of State in 1938 established a Division of Cultural Relations. In 1940 the Office of the Coordinator of Commercial and Cultural Relations between the American Republics now called Office of the Coordinator of Inter-American Affairs, was established with Nelson Rockefeller at its head. There is also an Interdepartmental Committee on Cooperation with the Latin American Republics, in which seventeen or eighteen government agencies are represented.

Older than any of these and forming a background for their development is the Pan American Union, founded in 1890 as the "Commercial Bureau of American Republics" following the first International Conference of American States. In 1902 the second conference of American states created the Pan American Sanitary Bureau, separate from the Pan American Union but cooperating with it and maintaining offices in the beautiful Pan American Union building, one of the show places of Washington. This bureau handles all medical and health questions that come to the union.

The Pan American Sanitary Bureau holds a conference every few years; the next will be in Rio de Janeiro in 1942. Between times the bureau calls to Washington health officials of the twenty-one republics for the Pan American Conference of Directors of Health. Thus the public health problems of the Western Hemisphere are discussed in an atmosphere of friendly and cordial cooperation.

The Rockefeller Foundation has had a powerful influence in developing mutual understanding between Latin America and the United States with its fellowships and study tours for health officials, its support of medical schools and public health institutions and subsidy of rural health organizations, as well as its direct scientific work.

More than twenty years ago, for instance, the foundation began to encourage an "institute of hygiene" at São Paulo, Brazil. Through the years it has quietly continued to help in similar ways. One of the latest developments is an arrangement concluded with the government of Ecuador for a national institute of hygiene at Guayaquil. The foundation's policy is to support such undertakings and gradually to withdraw as the authorities are able to take them over. Not only will it contribute equipment and a part of the funds for maintenance of the new institute until Ecuador assumes full responsibility five years hence, but it has awarded fellowships to young men to study in the United States before taking charge of its technical departments.

Spectacular among the foundation's activities in South America has been its fight against yellow fever. After ten years of work, it was thought that yellow fever had been eliminated from the Americas, but suddenly in 1928 the disease flared up in Brazil. The fight began all over again. Intensified studies in subsequent years have led to the discovery of a new type of jungle yellow fever and to the development of a vaccine. As a result of studies in Colombia in 1940 it is now pos-

sible by tests on animals to determine the risk to human beings entering a region. Formerly it was necessary to wait until some one died of the disease before the danger was discovered.

Parallel with the activities so far outlined, private medical organizations were making many contributions to inter-American acquaintance. Most of us have been blissfully ignorant of these efforts, which were unheralded outside the medical profession.

From 1919 through 1928 the American Medical Association published an edition in Spanish of its official publication, *THE JOURNAL*. Its library has for many years indexed the leading medical journals of the rest of the hemisphere and *THE JOURNAL* each week has published abstracts of their most important articles, thus bringing the best medical literature published in Spanish and Portuguese on this side of the Atlantic to the attention of North American physicians.

The American College of Surgeons has since its founding in 1913 offered fellowship to Central and South American surgeons, and its officers made numerous tours to the Latin American countries in the interest of closer ties among colleagues of the hemisphere. Recently the college reported that it has two hundred and forty-six Latin American fellows, of whom a goodly number attended the annual congress in Boston in November.

For the past five or six years the American Hospital Association has had a committee on Latin American relations. Now this association is sponsoring an Inter-American Hospital Association, formed last September in Atlantic City. The American Public Health Association opened its membership to health authorities of Mexico, Cuba, Central America and South America more than fifty years ago and now has members in sixteen of those countries. Twenty-four public health officials of Latin American countries were special guests at the October meeting of the association at Atlantic City.

CONVENTIONS

There have been Pan American medical congresses from time to time for many years. The American Medical Association took the lead in organizing an important one as far back as 1893 in Washington, D. C., inspired by celebrations of the four hundredth anniversary of Columbus's voyage to the New World. *THE JOURNAL* of Sept. 9, 1893 made this editorial statement:

The Congress is looked upon as the initial step towards cementing the grand brotherhood of American States into commercial and professional union. Political union may not be desirable, but commercial and professional unity of action will develop the Americas as nothing else could develop them. The republican idea, too, will gain new strength throughout the world as an indirect effect of these periodical exhibitions of power.

Another passage that sounds as if it might have been written during the present recrudescence of interest in inter-American relations occurred in the pre-

dential address of Dr. William Pepper, then president of the University of Pennsylvania, who quoted advice from Benjamin Franklin:

It is a true saying that to know is to excuse and more than this, in regard to nations if not strictly in regard to individuals it may be added that to know is to love. We turn with quickened interest to the sage advice of the illustrious Franklin, who in 1749 embodied in his plan for the organization of the University of Pennsylvania an earnest advocacy of the thorough teaching of the Spanish and Portuguese tongues as likely to hasten the development of those reciprocal relations which he foresaw would inevitably arise between the countries of the two Americas.

This brilliant 1893 congress was the beginning of a series that ended during the upheaval of the World War.

Five Pan American congresses on tuberculosis have been held, the latest in October 1940 in Buenos Aires and Córdoba, Argentina. A North American physician who attended the recent one wrote later of the Argentine physicians: "Their hospitality is magnificent and their desire to exchange ideas seems genuine. It is my belief that we should reciprocate to the full extent that they desire our participation."

The second Pan American Congress of Endocrinology was held in March of this year (1941) in Montevideo, Uruguay. Endocrinologists from many parts of the United States made this trip.

Back in 1925 a group of New York physicians organized the Pan American Medical Association as an agency through which they could promote inter-American congresses and extend courtesies to visiting physicians from the other American republics. Seven congresses have been held, some of them in connection with cruises of several weeks' duration. On these trips physicians traveled first to Havana, then Panama, Mexico City, Dallas, Venezuela, Brazil and in 1938 to Havana and the West Indies again. The eighth congress is scheduled for Buenos Aires in August 1942.

Several years ago a number of New York physicians interested in physical therapy organized the Latin American Congress of Physical Therapy, X-Ray and Radium, which visited Mexico City for its first meeting and a few years later took a similar trip to Guatemala City. Still another society that has devoted itself to Latin American friendship is the International Spanish-Speaking Association of Physicians, with headquarters in New York.

Medicine has played a part in several general congresses in which the Americas have joined for the promotion of both scientific knowledge and mutual acquaintance.

The American Scientific Congress, which met with great pomp in Washington in May 1940, was the eighth of a series that began in 1898. One of its eleven sections presented an impressive program on public health and medicine. An announcement of one of the earlier congresses in this series indicates that friendship between the Americas has long been a hope of scientific men, expressed in this declaration:

These Pan American Scientific Congresses, as must be apparent to your discernment and to that of your fellow members, are of the utmost and ever increasing importance both in the ideological field and in connection with international solidarity.

Seven meetings have been held of the Pan American Child Congress, which devotes a major part of its program to discussions of health and medical problems. The eighth congress was to have been held in San José, Costa Rica, in 1939, but events of that fateful period

caused its postponement. Before the United States entered the war, plans were in the making to hold the deferred meeting in Washington next year.

With the experience of these earlier undertakings as a basis, Pan American relations in medicine have expanded in unison with the general awakening of the North and the South to the need for common action.

The tragedy of Europe has extinguished for the time being and possibly for years to come many international medical organizations which brought together medical men of all countries every few years and thus contributed to the worldwide dissemination of medical knowledge. Forced abandonment of international gatherings has given still another stimulus to intermingling of North, South and Central Americans. Physicians who once enjoyed meeting their colleagues from all continents have begun to build up Pan American assemblies to take the places of those of worldwide membership.

When the last International Congress of Microbiology met in New York in September 1939, just as war broke over Europe, an Inter-American Society of Microbiology was organized on the spot. Plans were started for a congress in Rio de Janeiro in 1942.

That same fall eye specialists attending the American Academy of Ophthalmology and Otolaryngology, seeing that the International Congress of Ophthalmology would be disrupted, laid plans for a Pan American Congress of Ophthalmology.

That meeting, held in Cleveland in October 1940, brought about twenty eye specialists from Brazil, Cuba, Chile, Costa Rica, Puerto Rico, Colombia, Guatemala and Panama. It resulted in "a definite and marked entente cordiale among the ophthalmologists of North, South and Central America," those who carried the meeting to a successful conclusion reported afterward. A permanent organization was formed and many plans are now being evolved for exchanges of medical journals, exchanges of students and another meeting in Montevideo, Uruguay, in 1943.

The Catholic Hospital Association welcomed to its meeting in Philadelphia last June representatives of ten republics of the South. There it was pointed out that hospitals were founded in the Western Hemisphere by Spanish pioneers long before the early settlements in the eastern part of North America. Plans to admit hospitals of Mexico to the association are to be presented next year and, as occasion arises, those of the South American republics will also be admitted, it was predicted.

Another step made by hospital groups was the Inter-American Institute for Hospital Administrators held in December 1940, when hospital officials from ten countries in the Caribbean area gathered in the beautiful old city of San Juan, Puerto Rico, for two weeks of discussions. Puerto Rico is in the unique position of belonging both to the United States and to the Ibero-American countries, to the North by political ties and to the South by ties of language and origin.

"A cultural, social and scientific bridge between the Americas passes through the West Indies, and the medical pillars of this bridge were unquestionably strengthened by the Inter-American Institute," one of the participants reported.

Cancer specialists recently announced a Pan American League Against Cancer to replace the International Union Against Cancer, now unhappily in eclipse because of the war. The league is working toward a cancer

congress to be held in Brazil in 1942. Radiologists are also exploring the idea of a Pan American congress.

The International College of Surgeons turned its 1941 assembly into an Inter-American meeting in Mexico City with speakers from a dozen or more of the Latin American countries on its program. Dentists too are contributing to the campaign for mutual acquaintance. The Mexican Association of Orthodontia organized its third "medicodental" convention in Mexico City in June and invited not only dentists but many physicians from the United States to present papers.

Now comes the American Medical Association, with its sixteen scientific sections representing all specialties in medicine, with plans to make its ninety-third annual session in Atlantic City in 1942 a Pan American meeting, almost fifty years after the great Columbian celebration in Washington.

The Board of Trustees at the Cleveland meeting last June reported that it had been "impressed with the importance of facilitating further cooperation of this type in the interest of scientific advancement and unity of the American continents."

The House of Delegates, the official legislative body of the Association, adopted the following recommendation introduced by the Council on Scientific Assembly, the group which plans the scientific sessions:

The Council on Scientific Assembly recommends to the House of Delegates of the American Medical Association that the annual meeting to be held in Atlantic City in 1942 be made a Pan American meeting and that representatives from all South and Central American countries, Mexico, Cuba and Puerto Rico be invited to attend and to participate in the scientific session program.

The Delegates then asked the Trustees to appoint a Commission on Pan American Relations. This was done immediately and the group has already started that work behind the scenes which must precede a successful convention.

Convention visits are of course fleeting. They are serving as an introduction, but other things are being done on a personal basis. The U. S. Department of State began last January a policy of inviting distinguished leaders of the other American republics to visit the United States for two or three months each. There have been several physicians among these guests of the government. A professor of psychiatry in São Paulo, Brazil, who is also president of a Brazilian organization for advancing cultural relations with the United States, came in the spring and an Argentine radiologist in the summer. Both attended medical meetings and visited hospitals and universities.

Besides these visitors coming by official arrangements, many are coming on their own initiative. One alert Brazilian eye specialist this year made his fourth annual trip to attend a convention in his field.

SCHOLARSHIPS

Meanwhile the "norteamericanos" are finding their way south, some under the State Department's travel grants, others under diverse auspices. Already mentioned are those who have attended Pan American conventions. In the past few months a Harvard teacher and one from Cincinnati have gone to Bogotá, Colombia, to lecture to physicians and medical students, and a Philadelphia specialist to advise on the building of a tuberculosis sanatorium. The president of the Pan American Congress of *Ophthalmology* flew to Brazil in July to read a paper at the national meeting of eye specialists in Rio de Janeiro.

Most productive perhaps of all means of interchange between the Americas is the exchange of students and professors. The State Department reported a few months ago that about fourteen hundred students from the other republics were in the United States in 1940-1941.

Long before the present awakening, or reawakening, of interest, certain far seeing and wide ranging agencies were encouraging students of the Americas to study in other parts of the hemisphere. The International Institute of Education, the Rockefeller Foundation and the Guggenheim Foundation have been actively promoting the interchange for years, and their efforts have increased many fold in the recent past.

Cornell University Medical College, New York, and the University of Havana have an interesting arrangement for exchanging students and faculty members for several weeks at a time for periods of study. The plan has apparently worked well, for it was begun with an agreement for only one year and was continued last year for another period.

Now the governments of the republics are taking a hand. Several months ago the State Department reported that fourteen graduate students were studying in the United States under the terms of the Convention for the Promotion of Inter-American Cultural Relations, signed at Buenos Aires in 1936. Three of this group are physicians, including one from remote Paraguay.

Another government project is under theegis of the U. S. Public Health Service, which has made available fellowships "in the sciences related to public health." These cover a wide field, including medicine, dentistry, pharmacy, nursing, sanitary engineering, vital statistics and bacteriology. The fellows are selected by the Surgeon General on recommendation of the Pan American Sanitary Bureau with the approval of the Secretary of State. Newest of all are the hospital internships arranged for graduates of Latin American medical schools through the cooperation of the Office of the Coordinator of Inter-American Affairs (popularly called the Rockefeller Committee), the Pan American Sanitary Bureau and the participating hospitals and clinics. Thirty-seven medical graduates arrived in August to begin work under this arrangement.

In recent months numerous fellowships and scholarships have been offered by special groups. The American Foundation for Tropical Medicine has established fellowships that will allow young physicians to study tropical medicine at Tulane University in New Orleans. The Cleveland Clinic has invited a young Argentine surgeon to spend a period of study on its staff. The Dazian Foundation, bequest from the fortune of a famous theatrical costumer, is financing a fellowship at Mount Sinai Hospital, New York.

STUDY OF LANGUAGE

Efforts to foster more intimate relationships in the field of medicine and its related sciences are taking other forms too. Several enterprising organizations have issued some of their literature in Spanish in order to make special information available to Spanish and Portuguese speaking physicians. If one may judge from remarks heard in a recent discussion, this service will be appreciated. At a gathering in honor of a group of Mexican educators, one of the visitors was asked whether medical textbooks of the United States were widely used in Mexico. Regretfully he replied that they were not, first, because they were too expensive and, second, because too few physicians in Mexico read English.

As to the language barrier, it may be said that this is being overcome on both sides of the border. This same group of Mexicans reported that English is now a required subject in the schools of Mexico. Most of the visitors who come from the other republics have bestirred themselves to learn English either in school or as a prerequisite to their trips.

Now in the English speaking part of the hemisphere, where the population has been so predominantly of the English tongue that it has never been forced to learn other languages, one hears of Spanish and Portuguese classes on every side. A group of Chicago physicians has engaged a Spanish teacher to come to their hospital several times a week and put in an hour or so drilling the doctors in order that they may better understand and deal with their Spanish speaking students.

A word just here in favor of Portuguese, which seems to have eluded North Americans almost entirely. Brazilians point out that South America has a Portuguese speaking population practically as large as that which speaks Spanish and they cannot help feeling that at least part of the translations and the lessons now in progress should be in Portuguese.

What of the conventions in which physicians of three languages mingle? This problem was admirably solved at one meeting by the use of lantern slides. Condensed versions of all papers were translated into Spanish or English, as was necessary, and these versions were shown on slides, giving summaries in the other language as the speaker progressed. The young woman who made the translations sat by the projector with a full copy of the paper and carefully listened as she directed the placing of the slides on the screen.

Returning to the recital of some specific things that have been done in the matter of publications: First, perhaps, should be mentioned the *Bulletin of the Pan American Sanitary Bureau*, which has long been published in English, French, Spanish and Portuguese. The U. S. Pharmacopeia, vast official list of drugs used in North American medicine, appeared in Spanish for Pan American use in 1938. *Modern Hospital*, a monthly magazine, published in 1940 "El Libro del Hospital Moderno," a reference book on hospital practice. The National Foundation for Infantile Paralysis this year issued its valuable little pamphlet "Nursing Care of Patients with Infantile Paralysis" in Spanish.

STRENGTHENING INTERNATIONAL TIES

The *American Review of Tuberculosis* began in October to publish summaries of its articles in Spanish. "It is hoped that this will increase the usefulness of the *Review* for our Latin American colleagues and stimulate their interest in the work published in the *Review*," the announcement said. "It should further strengthen the international ties of tuberculosis work."

Almost every one knows that the matter of unfavorable exchange of money is a standing difficulty of the Latin American countries in their dealings with the United States. At least one scientific group has made a move to alleviate this handicap in its field. The trustees of *Biological Abstracts* have offered to reduce the price of that publication to any one who wishes to send a set to a Latin American institution. It has been found that about one hundred and fifty research and educational institutions in Latin America did not subscribe to this tool of the scientist either because they did not have funds or because of the inequality of exchange.

More thinking along this line appeared in a letter to *Science* not long ago. The writer observed that few North American scientific periodicals go to Latin America and thought one reason might be the subscription rates, extremely high when translated into Latin American currencies. He had an idea that societies which could afford it might establish "exchange memberships" with similar organizations in the other countries. The exchange members would receive extra copies of their journals to be mailed to the members abroad, who would do the same with their periodicals. He also thought some societies might set up subscription rates in the currencies of the Latin American countries.

A different step in practical collaboration was taken recently by the University of California when it began small shipments to Lima, Peru, of radioactive phosphorus produced in the university's pioneering radiation laboratory by the cyclotron. This makes it possible for Peruvian medical authorities to try the radioactive material as it is being cautiously tried in this country in the treatment of cancer, leukemia and other diseases in which radium itself has been found beneficial. The artificially made radiations last only about two weeks, but air transportation takes the phosphorus to Lima within two or three days after its manufacture, leaving about ten days in which it is usable.

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Bills Introduced.—H. R. 6316, introduced by Representative Martin J. Kennedy, New York, provides compensation for injuries or death sustained by volunteer civilian defense workers in line of duty. H. R. 6324, introduced by Representative Ditter, Pennsylvania, provides that each person who enters into the armed forces of the United States shall be given a physical examination by medical officers at the time of entry into service. On the termination of such service, the bill provides, each person shall be given another physical examination by medical officers and a record shall be made of the findings of such examination and of any injuries, illnesses or disabilities suffered by him during his period of service. Each person who enters into service must be given a medical statement showing any

physical defects noted either on the examination given at the time of entry into service or on the examination given at the termination of the service.

DISTRICT OF COLUMBIA

Bills Introduced.—S. 2183, introduced by Senator McCarran, Nevada, proposes to amend the healing arts practice act by providing for the annual registration of licentiates and by imposing a \$2 annual registration fee. H. R. 6297, introduced by Representative Robinson, Utah, provides for the issuance of a license to practice chiropractic to Wesley K. Harris. H. R. 6344, introduced by Representative Reece, Tennessee, provides for medical examinations of persons charged with driving while under the influence of liquor.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

Changes in Health Personnel.—Dr. Ralph L. Best, Drumright, Okla., has been made health officer of Greene County with headquarters in Eutaw.—Dr. Corinne S. Eddy, Centerville, has been appointed health officer for Bibb County; she was formerly connected with the unit in Cleburne County.

Quarters for Industrial Hygiene Division.—Plans have been announced to move the state division of industrial hygiene from Montgomery to Birmingham, with space in the city hall building, where a laboratory will be installed. Dr. Edwin H. Place, Montgomery, was recently placed in charge of the division. The change is being made because Birmingham is the most logical center of industrial activity and because of demands in connection with the defense program, it was stated.

CALIFORNIA

Personal.—Dr. Ladislav Stofa, Marysville, has been named medical superintendent of Yuba County Hospital, Marysville.—Dr. Charles H. Kellaway, director of the Hall Research Institute, Melbourne, Australia, was a recent visitor at the University of California Medical School, San Francisco.

Buenos Aires Physician Chosen Herzstein Lecturer.—Dr. Eduardo Braun-Menéndez, lecturer in physiology and director of cardiovascular investigations, Institute of Physiology of the University of Buenos Aires Faculty of Medical Sciences, has been chosen to deliver the Herzstein Lectures this year. The lectures are delivered on alternate years under the direction of the University of California Medical School and Stanford University School of Medicine, San Francisco. This year they will be given at the University of California, extension division auditorium, March 9-13. Dr. Braun-Menéndez's topic will be "Experimental Renal Hypertension." The Herzstein lectures were established in 1929 under a provision of the will of the late Dr. Morris Herzstein of San Francisco.

CONNECTICUT

State Society Creates Associate Membership.—To permit medically prominent persons in Connecticut who are not licensed to practice in the state to join with the state medical society in furthering its objectives, the society amended its by-laws at its annual session in 1941 to provide for associate membership. As a result of this action the state medical journal for January announces the following associate memberships:

Harold S. Burr, Ph.D., E. K. Hunt professor of anatomy, Yale University School of Medicine, New Haven.

Dr. John F. Fulton, Sterling professor of physiology at Yale medical school.

Dr. Howard W. Haggard, director of laboratory of applied physiology at Yale University.

Ira V. Hiscock, C.P.H., professor of public health at Yale medical school.

Dr. Cyril N. H. Long, Sterling professor of physiologic chemistry at Yale medical school.

Friend Lee Mickle, M.Sc., director of bureau of laboratories of the Connecticut State Department of Health, Hartford.

William C. Welling, B.A., director of the bureau of vital statistics of the state department of health, Hartford.

DISTRICT OF COLUMBIA

Guest from Haiti.—Camille Lherisson, D.P.H., professor of biology, National School of Medicine, Port-au-Prince, Haiti, has arrived in Washington at the invitation of the U. S. Department of State to visit schools of medicine and departments of biology throughout the country. Dr. Lherisson received his degree in public health at Harvard University. He also studied at McGill University Faculty of Medicine, Montreal, Canada.

Garrett Resigns as Health Security Administrator.—Mr. Ross Garrett, administrator of Health Security Administration since its organization in 1938, has resigned. Mr. Garrett organized the Central Admitting Bureau for Hospitals and the Medical Dental Service Bureau in 1935. These organizations were consolidated in 1938 and became known as the Health Security Administration. Mr. Garrett has set up offices in Washington in the Medical Science Building and, according to his letterhead, renders consulting service in hospital and health activities.

ILLINOIS

New Director of Tuberculosis Control.—Dr. Edward K. Steinkopff, Milwaukee, medical consultant to the Anti-Tuberculosis Association of Wisconsin, has been appointed chief of the division of tuberculosis control of the Illinois State Department of Health, effective February 1, with headquarters in Springfield. The appointment inaugurates a new program of case finding and tuberculosis control in the state, based on an expected increase in the incidence of tuberculosis anticipated usually under war conditions. In announcing Dr. Steinkopff's appointment, Dr. Roland R. Cross, Springfield, state director of public health, stated that provisional tabulations show that there was 10 per cent more tuberculosis reported in the state in 1940 than in 1939 and perhaps 15 per cent more in 1941 than in 1940. Dr. Steinkopff graduated at the University of Illinois College of Medicine in 1929.

Chicago

Branch Meetings.—Dr. Roy R. Kracke, professor of pathology and bacteriology, Emory University School of Medicine, Emory University, Ga., discussed the "Effect of Drugs on the Hemopoietic System" before the North Suburban Branch of the Chicago Medical Society, January 8.—Dr. Alfred W. Adson, Rochester, Minn., addressed the North Shore Branch, January 6, on "Diagnosis and Treatment of Protruded or Ruptured Intervertebral Disk."

New Executive Appointments at St. Luke's.—Dr. Ambrose P. Merrill Jr., assistant director of St. Luke's Hospital, has been appointed medical director of the hospital, a newly created position. Leo M. Lyons, city relief commissioner since July 1936, has been appointed executive director, effective February 1. He will be directly responsible to the president of the hospital for its general management. Mr. Lyons began his public career in the Rockford public schools, where he was director of health education and recreation from 1915 to 1930.

Personal.—George F. Forster, Ph.D., has resigned as assistant chief of the division of laboratories, Illinois State Department of Health, to become associate professor of bacteriology in Loyola University School of Medicine, effective January 1. Dr. Forster received his Ph.D. degree at the University of Wisconsin, Madison, in 1922.—Fred C. Koch, Ph.D., Frank P. Hixon distinguished service professor emeritus of biochemistry and recently retired as chairman of the department of biochemistry, University of Chicago, has been elected an honorary foreign member of the National Academy of Medicine of Buenos Aires.

Research Committee on Cancer.—The University of Chicago announces four new appointments to its committee on cancer: Dr. William Bloom, professor and chairman of the department of anatomy; Earl A. Evans Jr., Ph.D., associate professor of biochemistry; Carl R. Moore, Ph.D., professor and chairman of the department of zoology, and Dr. Arno B. Luckhardt, professor of physiology. The new appointments bring to eighteen the committee members now engaged in basic research on cancer. The committee was created in 1938 to correlate the university's diverse research facilities in a clearing house for the thirteen departments, ranging from physics to surgery, which are participating in the research. The first gift the committee on cancer received was one of \$2,250 to establish a lectureship on cancer. This gift was made by the Educational Association on Cancer, an organization of Chicago women which for many years has been interested in the acquisition and dissemination of information on cancer.

INDIANA

Program on Nutrition.—At a meeting of the Indiana State Nutrition Council in Indianapolis on November 29 Dr. John W. Ferrer, Indianapolis, director and secretary of the state board of health and chairman of the council, appointed five subcommittees to organize a statewide educational program and plan a state nutrition conference.

State Board Creates Public Relations Post.—Mr. Creath Smiley, who has been associated with the state department of public welfare, has been appointed public relations counsel for the state department of health, a newly created position. Mr. Smiley has been handling radio and newspaper publicity for the department of welfare. In his new position he will prepare interpretative articles for state newspapers and magazines and act in an advisory capacity in matters relating to public relations. He graduated at the Indiana University School of Journalism in 1938.

Annual Secretaries Conference.—The Indiana State Medical Association announces its annual secretaries' conference, to be held at the Indianapolis Athletic Club, Indianapolis, January 25. Among the speakers will be:

Clarence A. Jackson, Indianapolis, chairman and civilian defense director, Indiana Defense Council, What Is Expected of Physicians in the Plans for Civilian Defense?
Dr. Jonathan Forman, Columbus, Ohio, Methods in Securing an Enabling Act for Prepaid Medical Care.
Dr. Samuel F. Seeley, major, medical corps, U. S. Army, and executive secretary, Procurement and Assignment Service for Physicians, Dentists and Veterinarians, Washington, D. C., Future Needs of the United States Army as to Physicians.
Dr. Charles H. Phifer, Chicago, president of the Illinois State Medical Society, Social Security Medical Problems.

The annual dinner in the evening will be addressed by General Lewis B. Hershey, director, Selective Service System, Washington, on "Procurement and Assignment of Physicians for Defense."

IOWA

Interprofessional Meeting.—The fifth annual state meeting of the Iowa Interprofessional Association will be held at Des Moines, January 27, with Mr. L. L. Eisentraut, Des Moines, president. Other speakers will be H. D. Bergman, D.V.M., Amcs, on "Interprofessional Relations and Cooperation"; Dr. James P. Leake, Washington, D. C., U. S. Public Health Service, encephalitis, and Adolf Eichhorn, D.V.M., Beltsville, Md., director of animal disease station, Bureau of Animal Industry, encephalomyelitis.

Society News.—Dr. M. Herbert Barker, Chicago, discussed hypertension before the Linn County Medical Society in Cedar Rapids, January 8.—Dr. Lester R. Dragstedt, Chicago, addressed the annual dinner of the Bremer County Medical Society in Waverly, December 8, on "Advances in Treatment of Cancer of the Gastrointestinal Tract."—The Cass County Medical Society was addressed in Atlantic, December 19, by Dr. Harry B. Stokes, Omaha, on bronchoscopy.—Dr. Leon S. McGoogan, Omaha, discussed "Operative Office Gynecology" before the Cerro Gordo County Medical Society, December 9.—The Lee County Medical Society was addressed in Keokuk, December 17, by Drs. William W. Heyerdale on "Present Day Management of Varicosities and Stasis Complications of the Lower Extremities"; Jacob A. Barga, "Regional Enteritis," and Fred Z. Havens, "Malignancies of the Face and Mouth." All are of Rochester, Minn.

KANSAS

Division on Public Health Information.—The Kansas State Board of Health, Topeka, has established a new division on public health information for the extension of lay educational programs pertaining to exhibits, movies, pamphlets, news releases and radio programs on public health. Mr. Roy Oxendale, formerly Topeka representative of the United Press, has been appointed director of the new unit.

Neuropsychiatric Meeting.—The Missouri-Kansas Neuropsychiatric Association met at the Menninger Clinic in Topeka on December 12. The following Topeka speakers participated in a symposium on military neuropsychiatry, which constituted the program:

Dr. William C. Menninger, The Psychiatrist in Relation to the Examining Boards.
Dr. Henry Harlan Crank, Abbreviated Neuropsychiatric Examination for Use in Selective Service Examinations.
David Rapaport, Ph.D., Detecting the Feebleminded Registrant.
Dr. Robert P. Knight, Recognizing the Psychoneurotic Registrant.
Dr. Carl-Gustaf D. Tillman, Recognizing Schizoid and Preschizophrenic Personalities.
Dr. Edward D. Greenwood, Recognizing the Psychopathic Personality.
Dr. Merton M. Gill, Malingering.
Dr. Ernest Lewy, Neuropsychiatric Casualties and Compensation.
Dr. Robert P. Knight, Psychiatric Problems of the Armed Forces in Training and in Combat.
Dr. Lewis L. Robbins, Civilian Morale in Time of War and Preparation for War.

Dr. Alexander R. MacLean, Rochester, Minn., addressed the banquet in the evening on "Postural Psychoneuroses."

LOUISIANA

Portrait of Professor of Surgery.—A portrait of the late Dr. John Smyth, professor of clinical surgery, Tulane University of Louisiana School of Medicine, New Orleans, was unveiled recently in the Hotel Dieu library, which he established. The picture was the gift of Mrs. Jeanne Sully Smyth, widow of the physician. Dr. Smyth was visiting surgeon at Hotel Dieu for more than thirty years. Dr. Daniel J. Murphy, chairman of the hospital board, presided at the ceremonies; guests included Dr. Rudolph Matas.

MASSACHUSETTS

Personal.—Dr. Russell F. Sullivan, Brookline, visiting surgeon to the Boston City Hospital and specialist in orthopedics, has been appointed professor of orthopedic surgery, Tufts College Medical School, Boston. Dr. Sullivan graduated at Tufts in 1918.

Gift of \$50,000 to Tufts Medical College.—Two gifts totaling \$50,000 to Tufts College Medical School, Boston, have been announced. The Bingham Associates Fund, Bethel, Maine, gave \$25,000, and the trustees of a trust for charitable purposes created by William Bingham 2d of Bethel gave the other \$25,000. The gifts were designated for the building fund of the school and bring the total to \$500,000 in its current campaign for \$750,000, newspapers reported.

Health Center at Radcliffe College.—The new Radcliffe College Health Center, Cambridge, is nearing completion. Newspapers reported on December 28 that it will contain twenty rooms with facilities for laboratories, dispensary for students and including living quarters for two nurses and two maids, accommodations for twelve beds with a potential capacity of twenty, to be used for diagnoses and minor illnesses. Serious cases will be treated in Boston and Cambridge hospitals. The center will be headquarters for the annual physical examinations. Dr. Harriet L. Hardy, Cambridge, is college physician.

MINNESOTA

Chiropractor Sentenced.—Edward F. Jacobson, St. Paul chiropractor, pleaded guilty on December 9 to a charge of performing an illegal abortion and was sentenced to not to exceed four years in the state prison. The defendant offered to surrender his basic science certificate and license to practice chiropractic in the state if the court would suspend the sentence and place him on probation. Albin S. Pearson, judge of the district court of Ramsey County, told the defendant that the court could not show him any leniency because he had a previous conviction of practicing medicine without a license that grew out of a similar case.

MISSOURI

Neuropsychiatric Institute.—The fifth interstate neuropsychiatric institute will be held at State Hospital Number 2, St. Joseph, March 22-April 4, under the sponsorship of the American Psychiatric Association through its committee on psychiatric and medical education and financed in part by a grant from the Rockefeller Foundation. Lectures will be presented on neuroanatomy, neuropathology, psychobiology, psychotherapy, neurooentogenology, neurosurgery and electroencephalography as well as presentations of clinical psychiatric and neurologic problems and related subjects, according to the state medical journal.

NEW YORK

Postgraduate Course.—"The Treatment of Common Diseases" is the theme of a postgraduate course which opened on December 16 for the Schoharie County Medical Society, Cobleskill. The course was arranged by Dr. Clayton W. Greene, Buffalo, under the auspices of the Medical Society of the State of New York. The speakers, all of Buffalo, included:

Dr. Byron D. Bowen, Management of Diabetes with the Newer Forms of Insulin, December 16.
Dr. Abraham H. Aaron, Treatment of Epigastric Distress Following Meals, December 23.
Dr. Frank N. Potts, Treatment of Low Back Pain, December 30.
Dr. Greene, Treatment of Precordial Pain, January 6.
Dr. Earl D. Osborne, Treatment of Common Skin Lesions, January 13.
Dr. Greene, Use of Sulfanilamide and Drugs of That Group, January 20. This lecture is given under the cooperation of the state department of health with the state society.

New York City

Meeting of Chest Physicians.—The New York state chapter of the American College of Chest Physicians will present the following program at the Hotel Biltmore on January 23:

Dr. Louis H. Clerf, Philadelphia, Tracheobronchial Tuberculosis.
Dr. Julian Johnson, Philadelphia, Total Pneumectomy.
Dr. Samuel J. Kopetzky, Medical Preparedness.
Dr. Henry K. Taylor, Role of the Radiologist in the Diagnosis of Diseases of the Chest.

Dr. Nelson W. Strohm, Buffalo, is president of the state chapter and Dr. Arthur Q. Penta, Schenectady, secretary-treasurer.

Meeting on Hearing Aids.—An open meeting on hearing aids will be held at the Columbia University College of Physicians and Surgeons, January 19, to discuss deafness and hearing aids. Subjects will include "Physical Considerations in the Design of Hearing Aids," "Problems in Fitting Technic" and "The Marketing of Hearing Aids." Included among the speakers will be Drs. Edmund P. Fowler Jr. and Cornelius E. Hagan Jr. on "The Otologist's Responsibility in the Fitting of Hearing Aids."

Medical Research Fund.—Lucius N. Littauer has donated nearly \$25,000 in stocks and securities to New York University to establish a medical research fund at the college of medicine, according to the *New York Times*. The money will be used to create the Lucius N. Littauer Fund, the income to be expended "for research in psychiatry, neurology and related fields, in order to increase and diffuse knowledge of the biologic and other factors which influence thought and conduct, and thereby to prevent and correct abnormal human behavior through experimental and clinical approaches." It was also stated that "a fair yet liberal part of the income will be devoted to fellowships for graduate students in medicine of superior ability, to be known as 'Littauer Fellows,' to be trained to practice psychiatry and those branches of medical science concerned with the activities of the mind and the factors influencing it."

Dr. MacInnes Receives Nichols Medal.—The 1942 William H. Nichols Medal of the New York Section of the American Chemical Society has been awarded to Duncan A. MacInnes, Ph.D., since 1926 associate member of the Rockefeller Institute for Medical Research, in recognition of his "outstanding investigations on electrolytes and the development of technics which have immeasurably enriched both the theory and the practice of modern electrochemistry." A statement made by the jury of the award reads in part: "On the basis of these studies the electrode is now a recognized and dependable device which finds wide industrial use. More recently, Dr. MacInnes and his associates at the institute have turned their interest to the motion of biologically important solutions in an electric field, and their experimental investigations in electrophoretic phenomena have greatly increased our knowledge of the protein content of the blood serum." Dr. MacInnes received his Ph.D. at the University of Illinois in 1911.

Record Low Mortality Rate.—A total of 74,553 deaths occurred in the city in 1941, giving a rate of 9.9 per thousand of population, the lowest general mortality rate in the city's history, newspapers reported on January 1. The population was estimated at midyear at 7,521,000. The previous low death rate was 10 in 1938. A new low rate of 30.8 per thousand live births was set for infant mortality, and the maternal mortality rate of 2.2 (247 maternal deaths) per thousand live births is also an all time low rate for the city. The birth rate was 15.2 per thousand of population in 1941. In 1900 the birth rate was 34.5. According to the report, the decrease in deaths from pneumonia in the last ten years has been spectacular and is attributed largely to chemotherapy and serums. In 1941 the mortality rate was 45 per hundred thousand of population against 45.7 in 1940; in 1931 it was 132.2. There were 404 cases of infantile paralysis with eight deaths last year. The last previous epidemic was in 1935, when 2,054 cases and ninety-one deaths were recorded. Typhoid cases totaled 193 with thirteen deaths, which, according to the report, is an "excellent showing" for a city of this size. Twenty-nine of these cases had been imported on refugee ships from Europe. A slight increase in deaths from tuberculosis was noted, 3,365 in 1941 as against 3,323 in 1940, but defense activities were not considered responsible for the rise. Appendicitis deaths totaled 562, giving a rate of 7.5 per hundred thousand of population. This is a new low rate for this disease, but the report states that appendicitis remains a "serious health problem."

OHIO

Changes in Health Officers.—Dr. William E. Sovik has been appointed health officer of Campbell, succeeding Dr. Edward J. Reilly. Dr. Arthur B. Ream, Mechanicsburg, has been appointed health commissioner of Clermont County.

Industrial Physicians' Club.—The Cleveland Industrial Physicians Club was recently formed to exchange views and to study problems in this field, as a result of expanded industrial activities in defense work. Officers are Drs. Rudolph C. Engle, president; Nathaniel M. Jones, vice president, and Richard P. Bell, secretary-treasurer.

Dr. North Retires as Professor.—Dr. Emerson A. North has retired as professor of psychiatry at the University of Cincinnati College of Medicine, effective July 1, 1942. Dr. John Romano, instructor in medicine, Harvard Medical School, Boston, has been named to succeed Dr. North, who is retiring on account of poor health, it is reported. Dr. North has been a member of the Cincinnati faculty since 1923.

OKLAHOMA

Personal.—Dr. Lewis E. Emanuel, Chickasha, was reelected president of the Oklahoma State Hospital Association at the annual meeting in Tulsa, Nov. 14, 1941. — Dr. Lowell L. Stokes, Okmulgee, is to be director of a new health unit in Okmulgee County.

Society News.—The Carter County Medical Society was addressed, November 3, in Ardmore by Dr. Milton J. Serwer and Mr. R. H. Graham, both of Oklahoma City, on "Endocrine Treatment of Abortion" and "The New Reregistration Law and Its Benefits to Both the Medical Profession and the Laity"; Dr. John Hobson Veazey, Ardmore, discussed "Erythroblastosis Fetalis" with report of a case. — Dr. Donald W. Branham, Oklahoma City, addressed the Cleveland County Medical Society, November 13, in Norman on "Injuries of the Urinary Tract." — Dr. Ralph M. Alley, Shawnee, discussed "X-Rays in the Diagnosis of Tuberculosis" before the Pottawatomie County Medical Society, Shawnee, December 20.

PENNSYLVANIA

Society News.—Dr. Theodore O. Elterich, Pittsburgh, discussed "Blood Diseases in Childhood" before the Washington County Medical Society in Washington, January 14. — The Delaware County Medical Society was addressed in Chester, January 8, by Dr. Charles I. Stiteler, Chester, on "Wild Flower Photography in Kodachrome: An Interesting and Educational Hobby."

Philadelphia

Dr. Craig Appointed Director of Chest Clinic.—Dr. Frank A. Craig, assistant professor of clinical medicine at the University of Pennsylvania School of Medicine and the Medico-Chirurgical College, Graduate School of Medicine, University of Pennsylvania, has been appointed director of the clinic of the Henry Phipps Institute. According to an announcement, under the new assignment Dr. Craig is responsible for the supervision of the chest clinic of the institute, covering the collapse therapy division of the clinic, the division of public health nursing and the special diagnosis clinic, which has been under his own active direction.

Personal.—Dr. Esmond R. Long, professor of pathology at the University of Pennsylvania School of Medicine and director of the Henry Phipps Institute, recently returned after a three months trip in South and Central America. For two months in Colombia he was consultant to the Junta Construction of the San Carlos Hospital, a sanatorium-hospital to be built on the outskirts of Bogotá. Dr. Long was also in Panama, Venezuela and Costa Rica under the auspices of the Pan American Sanitary Bureau and the division of cultural relations of the U. S. Department of State and lectured before the National Medical Association of Panama, the Medical Association of the Isthmian Canal Zone, the Academy of Medicine and various groups of tuberculosis specialists in Caracas and the faculty of medicine and tuberculosis specialists in San José. — Dr. Louis H. Clerf has been appointed chairman of the Physicians Group of the United Charities Campaign. The appeal of this group will be centered on physicians in central Philadelphia, West Philadelphia and Germantown.

TEXAS

Courses for Continuation of Medical Study.—The Dallas Southern Clinical Society announces its midwinter courses for the continuation of medical study to be held in Dallas, January 26-28. The facilities of the society, the hospitals and clinics of Dallas and the Baylor University College of Medicine will be available. The courses have been designed for the general practitioner and the specialist; physicians who are members of their county medical societies are eligible to attend. The subjects will cover diseases of the chest and medical and surgical diseases of the gastrointestinal tract. Additional information may be obtained from the Secretary, Dallas Southern Clinical Society, 1133 Medical Arts Building. Dallas

VIRGINIA

Annual Spring Graduate Course.—The sixteenth annual spring graduate course in ophthalmology and otolaryngology will be given at the Gill Memorial Eye, Ear and Throat Hospital, Roanoke, April 6-11. Speakers will include Drs. George E. Shambaugh Jr., Chicago; George M. Coates, Philadelphia; Bennett Y. Alvis, St. Louis; Wendell L. Hughes, Hempstead, N. Y.; Edmund B. Spaeth, Philadelphia, and John R. Richardson, Boston.

WEST VIRGINIA

State Society Announces New Procedure for Annual Meeting.—At a meeting in Bluefield, December 13, the committee on scientific work of the state medical association adopted a new procedure for the program of the seventy-fifth annual session in White Sulphur Springs, July 13-15. All of the section meetings will be abolished, but each section will take over a specified session of the general meeting and conduct a round table presentation of some practical phase of its specialty for the general practitioner. All meetings will be in the nature of round table discussions and the entire program will be designed for the general practitioner. It is believed that the new arrangement will give each section a larger and more important field of service. A national leader in each specialty will be invited to lead the discussion on a specified topic assigned by the program committee, and from two to three section members will be given subtopics to develop following the presentation of the guest essayist. Following this symposium the round table discussion will be conducted.

HAWAII

Emergency Blood Bank.—Newspapers reported on December 24 that between three and four thousand donors had contributed to a blood bank since December 7, the day of the Japanese attack. Plans are under way to accumulate five thousand flasks within two months for use in transfusions.

Dr. Moorhead Honored for Service.—Dr. John J. Moorhead, professor of clinical surgery, New York Post-Graduate Medical School, Columbia University, New York, has been presented with a medal and etching by the Honolulu County Medical Society for his work in helping to care for the wounded following the Japanese attack on Oahu, December 7. Dr. Moorhead was in Honolulu as the guest of the society to deliver a series of twelve lectures when the attack took place. He returned to New York January 8. In a statement to the press, Dr. Moorhead stated that he was on his way to lecture before the Honolulu County Medical Society when he heard the sounds of explosions. "I heard the radio in my car say that the Japanese had attacked, but I went on to the hall and started my lecture," he said. "Then an official of the society came running down the aisle shouting that the Japanese were attacking and that ten surgeons were wanted at the Tripler General Hospital immediately. That was soon after 9 a. m. In twenty minutes I was in the hospital, performing some operations and directing others."

GENERAL

Special Society Election.—Dr. Willis D. Gatch, Indianapolis, was elected president of the Western Surgical Association at its meeting in St. Paul recently. Other officers are Drs. Elmer M. Jones, St. Paul, and E. Eric Larson, Los Angeles, vice presidents; Arthur R. Metz, Chicago, secretary, and Verne C. Hunt, Los Angeles, treasurer. The 1942 meeting will be in Memphis sometime in December.

Time Changed for Defense Health Broadcast.—Announcement is made of the change in time of the round table radio programs known as the National Defense Health Clinics, which are broadcast over the national network of the Mutual Broadcasting System. In the future the time will be 3:45 to 4 p. m. eastern standard time, Sunday afternoons. Mrs. Franklin D. Roosevelt will participate in the program on January 18.

Gallup Survey of Common Colds.—In the one week period ended December 24 a survey by the American Institute of Public Opinion, of which George H. Gallup, Ph.D., Princeton, N. J., is director, found colds reported in one third of American homes, with an estimated total of 18,000,000 persons afflicted, according to the *New York Times*, January 3. More than three million man days of work were lost in war industries or war connected industries from illness during December, and the common cold accounted for half of this lost time, it was stated. In the one week survey, ended December 24, the highest incidence of colds was reported among children under 10 years. Among the 18,000,000 cold sufferers in this period, about one in four was treated by a physician.

Conference on Tomorrow's Children.—At the recent third Southern Conference on Tomorrow's Children in Nashville, approval was given to the organization of a regional committee to coordinate programs and activities in eleven Southeastern states. Membership of the new committee will comprise representatives of the state leagues from Alabama, Arkansas, Florida, Kentucky, North Carolina, South Carolina, Tennessee, Virginia and West Virginia. Georgia and Mississippi, which have no state leagues at the present time, will be represented by selected interested citizens.

Changes in Status of Licensure.—The California State Board of Medical Examiners at a meeting in Sacramento recently took the following action:

Dr. Howard D. Mayers, Fall River Mills, license revoked Oct. 22, 1941, having been charged with habitual intemperance.

Dr. Frederick William Riley, Holy City, license revoked Oct. 23, 1941; charged with aiding and abetting an unlicensed individual, namely William F. Hoque, who operated the Valley Rest Home, Los Gatos, where patients were treated with an escharotic paste in an asserted "cure" of cancer.

Dr. Oscar Charles Long, Brawley, license restored Oct. 21, 1941 and placed on five years' probation without narcotic privileges and ordered to report at each Los Angeles meeting. The license was revoked on March 10, 1938.

Riboflavin Requirement for Enriched Flour Postponed to July 1, 1942.—Federal Security Administrator Paul V. McNutt issued an order, December 3, postponing to July 1, 1942 the effective date of the mandatory riboflavin requirement in the definitions and standards of identity for enriched flour, enriched bromated flour, enriched self-rising flour and enriched farina. All the other provisions of the definitions and standards of identity for these products, published in the *Federal Register* of May 27, 1941, became effective on Jan. 1, 1942. In taking this action Mr. McNutt made the following statement:

A thoroughgoing canvass recently has been made of the present and prospective production of synthetic vitamins, including riboflavin. At the present time the supply of riboflavin, in forms suitable for addition to enriched flour and like products, is not sufficient to permit the production of such foods on a scale which would meet current demands. Riboflavin will become increasingly available in the first half of 1942, and it appears that by July 1 there will be adequate supplies for the enrichment program. In the light of this situation I am postponing to July 1, 1942 the effective date of the mandatory riboflavin requirement in the definitions and standards of identity for enriched flour, enriched bromated flour, enriched self-rising flour and enriched farina.

FOREIGN

Deaths in Other Countries

Dr. Emile de Grösz, emeritus professor of ophthalmology and former dean of the University of Budapest Medical School; honorary fellow of the American College of Surgeons and of the American Academy of Ophthalmology and Otolaryngology; ex-president of the International Organization of the Campaign against Trachoma, died in Budapest, aged 76.—**Dr. Emile-Jean Moure**, clinical professor of otorhinolaryngology, faculty of medicine of Bordeaux University; in 1904 president of the International Congress of Otolaryngology at Bordeaux; founder and for a time editor of *Weekly Review of Otolaryngology, Rhinology and Laryngology*, died at Cannes on the Riviera, aged 86.

CORRECTION

The Kenny Method.—In the editorial in *THE JOURNAL*, December 6, a statement was made which indicated that massage was a part of the Kenny technic. Sister Kenny writes to the effect that, according to her concept, the cardinal symptoms of infantile paralysis are "muscle spasm, muscle incoordination and muscle alienation," and that massage does not have any part in her procedure. She states also that "The muscles affected are in spasm, and massage would be damaging as it shortens the muscles affected. Free movement is now allowed until this condition has been rectified and coordination restored. All early movements are carefully guided and controlled by the technician." *THE JOURNAL* expects to publish in the near future an outline of the technic.

Government Services

New Unit of Gerontology

Nathan W. Shock, Ph.D., assistant professor of physiology, Institute of Child Welfare, University of California, Berkeley, has been appointed senior psychophysicist in the National Institute of Health of the U. S. Public Health Service, Washington, D. C. According to *Science*, Dr. Shock is to be in charge of the experimental program of the unit on gerontology of the institute, which has established a laboratory in the Baltimore City Hospitals.

Nov. 29, 1941.

Satisfactory Report on the Public Health

In the House of Commons Dr. Howitt opened a debate on the health of the people. It was feared that there would be a tremendous number of cases of neurosis from bombing, but such cases have been few. The minister of health, Mr. Ernest Brown, said that, considering the disturbances in life which had taken place, the health of the nation had been surprisingly good. It was bad psychology to be always discussing epidemics except as this led to remedial action. We wanted to make as widespread as possible the services which made for the health of the nation and everywhere to keep the people fighting fit. Much was being done in this field. In the arcas to which children have been removed from towns because of the risk of bombing we were providing scores of new sick bays to deal with scabies and impetigo. In regard to the general health, the general death rate was 14.3 per thousand, but that figure was not comparable with the figures of recent years, as non-civilians had been excluded since the outbreak of war. The figure for 1939 was 12.1. The infantile mortality in 1940 was lower than the rate for any year previous to 1938. The maternal mortality rate declined to a new record of 2.61 per thousand labors, against 2.92 in 1939. The conditions of public health remained generally satisfactory. Early in 1940 there was an increase of cerebrospinal fever, but its recurrence had been less noticeable in the early part of this year. The minister of health said he would not cease to look for opportunities in war to find additional services which, when the war was won, would continue the great improvements in progress when it began. He hoped to give in a few weeks a much fuller report on the public health.

INCREASE OF TUBERCULOSIS

A previous minister of health, Mr. Macdonald, claimed that the public health was so good that it showed improvement under war conditions. One exception has to be made, but it is not important. There has been some increase in tuberculosis. In the House of Commons the minister of health stated that on the basis of provisional mortality figures for the years 1939 and 1940 the rate for pulmonary tuberculosis in England and Wales for the population as a whole was 9.7 per cent higher in the latter than in the former years, the highest rate of increase being 15 per cent in females between the ages of 15 and 25 years. In the first quarter of 1941 there was, however, a reduction of 7 per cent for the population as a whole and of 4 per cent for women between the ages of 15 and 25.

This special increase of tuberculosis in young females has led to some comment. In a letter to the *Times* Sir Ernest Graham-Little (dermatologist and member of parliament) states that the total deaths from tuberculosis in females of the ages of 15 to 25 years in 1938, the last prewar year, was 1,761, as against 2,073 in 1940, the latest year for which records exist. The same selective mortality was observed in the last war. Graham-Little states that, although much research was devoted to its explanation, the problem remains unsolved. He says that mortality from tuberculosis is generally accepted as an index to the level of nutrition and submits that one factor in this difference of incidence between men and women may lie in their different dietetic habits. More than one speaker in the debate in the House of Commons pointed out that too many young women are accustomed to make their midday meal of "tea and buns." The latter are made from white flour, which is of negligible nutritive value, consisting almost wholly of starch and stripped of all vitamin content.

Inefficient Steam Sterilization

A case of the rare condition puerperal tetanus was recorded by Maclean and Challen in the *British Medical Journal* (2:302 [Aug. 30] 1941). The symptoms began ten days after forceps delivery and suture of the perineum with the silkworm gut. Though a direct smear and culture of vaginal smear was negative for tetanus bacilli, it was concluded that infection took place through the lacerated vaginal tissues. The patient was admitted to the hospital fifteen days after delivery, and no knowledge regarding the asepsis of the obstetric procedure was obtainable. A foul sanguineous vaginal discharge, which appeared on the second day after admission, was considered strong evidence of the site of infection. This case is referred to in an editorial entitled "Inefficient Steam Sterilization" (*ibid.* 2:445 [Sept. 27] 1941). It is pointed out that Pulvertaft (*ibid.* 1:441 [Feb. 27] 1937) was able to attribute a case of tetanus after hysterectomy to infection from an unsterilized vaginal pad. This led to the appointment by the Royal College of Obstetricians and Gynecologists of a committee to investigate the possible transmission of anaerobic infections by surgical dressings, with special reference to vaginal pads as a source of tetanus. This committee found that brown cotton wool undergoes no chemical treatment and therefore contains bacteria from the soil in which it was grown. White cotton wool is bleached by boiling in alkali and subsequent treatment with chlorine, which sterilizes it, but after washing in water—a treatment which at the factory investigated loaded it with cocci, owing to the multiplication of these organisms in a softening plant—it is dried in a current of hot air. The blower fans in the premises examined were close to the floor in such a situation as to suck up dust. Cotton wool of course is an excellent filter for particulate matter in air. Sporogenous bacteria were in fact cultivated from all samples examined and the bacillus of tetanus from one. To filter air used for drying or to sterilize the material in bulk in the factory may or may not be possible. If not, cotton wool requires efficient steam sterilization before surgical use. The use of the autoclave in hospitals was found open to criticism. Some of those responsible did not know that overtight packing can prevent adequate penetration by steam, and the technic was unreliable in other ways. The committee recommended loose packing of drums, evacuation to a negative pressure of 20 to 25 inches of mercury, a steam pressure of 20 pounds for twenty minutes and a monthly bacteriologic test with spore bearing anaerobes.

Radium Therapy During the War

The bombing of cities has seriously interfered with radium therapy. The destruction of a radium containing apparatus would be not only a serious loss but a great danger. The scattering of the radium salt might render the locality dangerous for a long time if the salt could not be recovered. Since the outbreak of the war the radium stocks of the London hospitals have been buried in a specially constructed borehole extending to 50 feet below ground. A steel tube 70 feet long extends from outside the telerradium treatment room on the second floor and is sunk in concrete. The radium is kept in a special casket which can be rapidly raised or lowered by a steel hawser operated by a winch and a series of pulleys.

At the Royal Cancer Hospital, London, the use of radium in the form of surface or intravaginal applicators was abandoned temporarily in September 1940 owing to the continuous air attacks, but treatment by telerradium was not interrupted. Treatment of cancer of the skin and uterus was resumed in October, but the use of intrauterine and intravaginal applicators had the difficulty that removal whenever an air raid warning was sounded could not be done in less than two minutes, during which a large quantity of radium would be exposed to danger. To meet this difficulty not more than 90 mg. of radium

was ever left in use during an air raid, and the patient was kept in the safest part of the hospital—the ground floor of a five story ferroconcrete building. The war certainly has had a detrimental effect on radium treatment. Surgery or roentgen treatment had to supplant it to some extent and not with advantage. Also the migration of patients in consequence of air raids, the life in shelters led by many and the bombing of hospitals interfered with their attending hospitals. Also the encouraging increase of cases seen in the early stage received a setback.

BUENOS AIRES

(From Our Regular Correspondent)

Oct. 15, 1941.

Congress of Surgeons of Argentina

The thirteenth Argentine Congress of Surgery was held in Buenos Aires, October 5 to 10. Delegations from Brazil, Chile, Bolivia, Uruguay and Paraguay participated. The chairman, Dr. Arnaldo Caviglia, called attention to the dangers involved in the inadequate surgical training of rural physicians and demanded better training of students.

The first paper, on relapse of umbilical hernias, was given by Dr. Germán Taubenschlag. He designated the constitutional weakness of the wall as the cause of the recurrences. On the basis of embryologic studies and investigations on the physiologic functions of the abdominal muscles, he defended the point of view of the congenital origin of these hernias. Women with this type of hernia require surgical treatment; if they are obese, preliminary reducing treatment should be employed in order to avoid recurrences. In some cases a lipectomy is necessary as a preparatory operation. The speaker recommended transverse elliptic incisions and rejected those which conserve the umbilicus, except in cases in which the hernia is extremely small. Cotton thread is particularly recommended as suture material; it is the best nonresorbable material and causes the least inflammatory reactions. Drainage is to be avoided, even in case of extensive incision. After the operation an adequate rest period is necessary. The patient's constitution, constipation, births and premature getting up are the most important causes of recurrence.

The second paper, on recurrence of inguinal and crural hernias, was presented by Dr. Carlos I. Allende. He designated congenital and constitutional factors as the chief causes of relapse and then evaluated the anatomic and surgical conditions and the operations.

The subject of subphrenic abscesses was reviewed by Dr. Oscar Cames of Rosario. As regards treatment, he recommends the extrascrous, particularly the retroperitoneal, approach. He discussed prophylaxis of the abscess, giving attention to disorders that may cause it, that is, appendicitis and gastroduodenal perforation as well as hepatobiliary disorders. It is surprising how rarely these abscesses result from the perforation of a hepatic cyst or an anebic abscess. Diagnostic puncture is not without danger; it can be risked only in special cases and as part of the operation. The prognosis depends largely on early diagnosis. The dangers increase considerably if complications exist.

The paper on the last official subject, traumatic injuries of the menisci and the crucial and lateral ligaments of the patella, was presented by Dr. José Valls.

The final resolutions of the congress stressed the importance of special training in surgery with a corresponding certificate. This is considered indispensable also for the uniform regulation of the hospital career of surgeons.

The subjects planned for the next annual congress are non-traumatic compressions of the spinal cord, injuries of the thorax and acute pancreatitis.

Chilean Congress of Pediatrics

The Chilean Congress of Pediatrics, recently held in Valparaiso, recommended among other things that the Instituto Internacional Americano de Protección a la Infancia should make inquiries regarding nutrition in the different South American countries and suggest ways and means for the exchange of basic foodstuffs. Furthermore, in view of the general political conditions it is suggested to call a Congreso latinoamericano de medicina infantil, which is to meet in Buenos Aires.

The first paper, by Professor Scroggie, was on deficiency symptoms during childhood. These are relatively frequent in Chile. The symptoms are multiform, several of them characteristic for Chile. Pellagra is rarely observed; more frequent are protein, fat and vitamin hunger. Edemas, hyperkeratosis, atrophic skin, hypermelanosis and others are observed. Scroggie described a so-called scratch symptom observed by him: when the nail is drawn over the skin lightly and without pressure, a white line appears, which disappears again after three to twelve hours, whereas normally it should disappear in from fifteen to twenty minutes. At the end of twenty-four hours a crust or a crustlike line, interrupted by parts of normal skin, appears in place of the white line. This sign is caused by the hyperkeratosis, the atrophy of the epidermis and the infiltration of the corium. Many of these children have symptoms of sprue and of gastrointestinal infantilism such as distended abdomen, dolichocolon, dyskinesia of the intestine, profuse foamy stools of grayish white or brownish appearance with large quantities of fatty acids or soaps. In the treatment, blood transfusions or plasma infusions are of decisive effect. Proteins, carbohydrates and vitamins should be given.

Later the congress directed its attention to the problem of the care of prematurely born infants on the basis of 258 who were cared for in the Casa Nacional del Niño from 1931 to 1939. Premature births are caused by social and environmental factors. In the cases examined, causes prevailed which could have been avoided, such as tuberculosis and syphilis in the mother. One fourth of the prematurely born infants showed signs of nonviability; their mortality was one third. Of 130 prematurely born infants that were observed for eight months, 80 per cent had rickets. In the anemia of the prematurely born, the customary therapeutic measures are of no avail. Favorable, rapid and permanent results are obtained with blood transfusions. The total mortality reached 41.4 per cent; by improved care it could be reduced to 20 per cent in 1939. The chief causes of death were intercurrent infections, tuberculosis and syphilis; then followed debility and cerebral and umbilical hemorrhages. During the first two or three months only breast milk was given; however, it should be remembered that there are individual differences in the food requirements.

The third subject was empyema in children. It is most frequent in boys and occurs chiefly during winter; the right half of the thorax is mainly involved. The mortality is greatest in children below 2 years of age.

Marriages

CHARLES E. SAN, Bloomfield, N. J., to Miss Harriet L. Horovitz of Savannah, Ga., in Charleston, S. C., Aug. 28, 1941.

ISADORE JACQUES YETWIN, Waltham, Mass., to Miss Ruth Horovitz of Elizabeth, N. J., in Brooklyn, Dec. 21, 1941.

ALBERT E. ABRAHAM, Arlington, N. J., to Miss Henrietta T. Abrahams of East Orange, N. J., June 22, 1941.

ROBERT BOYD STITH JR., Florence, S. C., to Miss Finley Plunkett of Aiken in December 1941.

CLARENCE VERNARD HODGES, Chicago, to Miss Nelle Mae McAfee of Flossmore, Ill., recently.

BRUNO RIEMER, Romulus, N. Y., to Miss Katharine Kochler of New Rochelle, Aug. 22, 1941.

Deaths

Robert Coalter Bryan, Richmond, Va.; Columbia University College of Physicians and Surgeons, New York, 1899; since 1932 emeritus professor of genitourinary surgery at the Medical College of Virginia; member of the Medical Society of Virginia and of the Southern Surgical Association; past president of the American Association of Genito-Urinary Surgeons; fellow of the American College of Surgeons; served in the regular army during the World War and as a member of the American Red Cross Commission to Rumania; surgeon, Stuart Circle Hospital; member of the House of Delegates of the American Medical Association in 1919; visiting surgeon, Memorial Hospital; at one time one of the owners and chief surgeon at the Grace Hospital; aged 68; died, Dec. 24, 1941.

Charles Clagett Marbury • Washington, D. C.; Georgetown University School of Medicine, Washington, 1893; professor of clinical medicine emeritus at his alma mater since 1925, and from 1904 to 1925 professor of clinical medicine; fellow of the American College of Physicians; veteran of the Spanish-American and World wars; attending physician, Providence Hospital, from 1898 to 1931, chief of staff from 1920 to 1931 and since 1931 member of the consulting staff; since 1928 member of the consulting staff of the Central Dispensary and Emergency Hospital; member of the board of visitors and governors of St. John's College, Annapolis, Md., from Nov. 10, 1924, to March 8, 1938; aged 71; died, Dec. 10, 1941, of coronary thrombosis.

Francis Proctor Field • Surgeon Lieutenant Commander, United States Navy, retired, Parris Island, S. C.; Long Island College Hospital, Brooklyn, 1903; veteran of the Spanish-American War; appointed an assistant surgeon in the naval reserve force in 1917 and was commissioned as a lieutenant in the medical corps of the navy on Aug. 3, 1920; was promoted to the rank of lieutenant commander on June 30, 1931; placed on the retired list Sept. 1, 1940, but remained on active duty at the Marine Barracks; held the Nicaraguan Campaign Medal, the World War Medal and the Spanish-American War Medal for his service in the army; aged 65; died, Dec. 7, 1941, in the United States Naval Hospital of coronary thrombosis.

Loren Bascom Taber Johnson • Washington, D. C.; Georgetown University School of Medicine, Washington, 1900; formerly associate professor of psychopediatrics at his alma mater; veteran of the Spanish-American and World wars; at one time member of the District of Columbia Commission on Mental Health; member of the American Psychiatric Association; past president of the Clinico Pathological Society of Washington and the Washington Nervous and Mental Disease Association; president of the Washington Institute of Mental Hygiene; on the staffs of the Children's Hospital and the Garfield Hospital; aged 66; died, Dec. 14, 1941, in the Emergency Hospital of carcinoma of the stomach.

Lyman Luther Daines, Salt Lake City; Rush Medical College, Chicago, 1931; member of the Utah State Medical Association; dean and professor of bacteriology and pathology at the University of Utah School of Medicine; formerly served as assistant in bacteriology and pathology at the University of Illinois College of Medicine, Chicago; was a special expert for the U. S. Public Health Service; carried on investigations in leprosy and tuberculosis; past president of the Utah Academy of Sciences and the Utah State Public Health Association; formerly member of the city board of health; pathologist, Latter-Day Saints Hospital and the Holy Cross Hospital; aged 58; died, Dec. 12, 1941, of coronary occlusion.

Charles Bradford Sylvester • Portland, Maine; Medical School of Maine, Portland, 1889; past president of the Maine Medical Association, Oxford County Medical Society and the Cumberland County Medical Society; was chairman of the tuberculosis division and past president of the Maine Public Health Association; formerly a member of the board of directors of the National Tuberculosis Association; fellow of the American College of Physicians; served during the World War; was a captain, a major and lieutenant colonel in the United States Army Medical Reserve, retired in 1927; for many years consultant, Maine General Hospital; aged 76; died, Dec. 18, 1941.

Emil Theodor Mueller • North Tonawanda, N. Y.; Universität Heidelberg Medizinische Fakultät, Baden, Germany, 1906; member of the American Society of Clinical Pathologists;

medical missionary in Africa from 1909 to 1914; assistant pathologist, New York State Institute for the Study of Malignant Diseases, Buffalo, from 1915 to 1923; pathologist, J. N. Adam Memorial Hospital, Perrysburg, 1923-1924; aged 61; since 1924 pathologist, and past president of the staff of the Deaconess Hospital, where he died, Dec. 17, 1941, of coronary occlusion.

James Joseph Duffy • New York; Harvard Medical School, Boston, 1919; assistant professor of radiology at Cornell University Medical College; member of the American Radium Society; fellow of the American College of Surgeons; associate attending surgeon, Memorial Hospital for the Treatment of Cancer and Allied Diseases; consultant, New York Infirmary for Women and Children, New York, St. John's Long Island City Hospital, Long Island City, and St. Agnes Hospital, White Plains; aged 49; died, Dec. 14, 1941.

Edward Francis Dean, Denver; University of Denver Medical Department, 1897; member of the Colorado State Medical Society; served during the World War; formerly associate professor of clinical surgery at the University of Colorado School of Medicine; fellow of the American College of Surgeons; past president of the Denver County Medical Society; surgeon, St. Luke's, Mercy and Denver General hospitals; aged 67; died, Dec. 4, 1941, of uremia and prostatic obstruction.

Walter Dean Murfin, Decatur, Ill.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1910; member of the Illinois State Medical Society; past president and secretary of the Macon County Medical Society; served during the World War; aged 54; died, Dec. 10, 1941, in St. Mary's Hospital.

Francis Henry Mosse, Tsinan, Shantung, China; L.R.C.P., London, England, M.R.C.S., of England, 1913, and M.R.C.P., of London, England, 1918; representative of the Church of England in the Union work at Chefoo University; aged 56; died, Dec. 6, 1941, in St. Mary's Hospital, Minneapolis, of pulmonary tuberculosis.

Kenneth Rush Bell, Sanford, Fla.; Emory University School of Medicine, Atlanta, Ga., 1928; member of the Florida Medical Association and the Southeastern Surgical Congress; at one time instructor in gross anatomy and assistant in surgery at his alma mater; aged 39; captain, medical reserve corps, United States Army, stationed at Camp Claiborne, La., where he died, Dec. 4, 1941.

Albert Letherland • Harrisville, N. Y.; Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1909; formerly county coroner; on the staff of the Lewis County General Hospital, Lowville, and the House of the Good Samaritan, Watertown; aged 61; died in December 1941 of coronary thrombosis.

Walter J. Kurtz, Howard, Pa.; Medico-Chirurgical College of Philadelphia, 1899; member of the Medical Society of the State of Pennsylvania; bank president, member of the county board of health, and school director; aged 65; died, Dec. 2, 1941, of pituitary tumor and myocardial degeneration.

George Arthur Craig, Swampscott, Mass.; Harvard Medical School, Boston, 1890; member of the Massachusetts Medical Society; clinical instructor in pediatrics at his alma mater from 1903 to 1908; aged 77; died, Oct. 24, 1941, in the New England Baptist Hospital, Boston, of bronchopneumonia.

Lemuel Ira Gist, Coldwater, Mich.; Eclectic Medical College, Cincinnati, 1927; member of the Michigan State Medical Society; veteran of the World War; county coroner; aged 46; died, Dec. 14, 1941, in the Community Health Center of burns received when a boiler exploded in his office.

Mindaugis Vincent Mikolainis, Hartford, Conn.; Columbia University College of Physicians and Surgeons, New York, 1933; member of the Connecticut State Medical Society; attending anesthetist on the staff of St. Francis Hospital; aged 30; died, Nov. 30, 1941, of acute leukemia.

James Percival Morrill • Paterson, N. J.; Yale University School of Medicine, New Haven, Conn., 1901; fellow of the American College of Surgeons; on the staff of St. Joseph's Hospital; aged 65; died, Dec. 14, 1941, of bronchopneumonia following bilateral ureteral obstruction.

William H. Thomas Hamill, Phillipsdale, R. I.; University of Vermont College of Medicine, Burlington, 1899; for many years health officer of the township of East Providence and formerly member of the school committee; aged 68; died, Dec. 3, 1941, of coronary thrombosis.

William A. Curtin, Syracuse, N. Y.; Syracuse University College of Medicine, 1887; member of the Medical Society of the State of New York; professor emeritus of clinical medicine at his alma mater; consulting physician, St. Joseph's Hospital; aged 79; died, Dec. 5, 1941.

Robert Maxwell Franklin @ White Plains, N. Y.; University of Tennessee College of Medicine, Memphis, 1925; was on the attending staff in tuberculosis and chest diseases at the Grasslands Hospital, Valhalla; aged 40; died, Dec. 5, 1941, in the Doctors Hospital, New York.

James Francis Dougherty, Richmond Hill, N. Y.; Bellevue Hospital Medical College, New York, 1897; served during the World War; at one time on the staffs of the Mary Immaculate Hospital, Jamaica, and St. Catherine's Hospital, Brooklyn; aged 67; died, Dec. 5, 1941, of chronic myocarditis and nephritis.

James William Morris @ Safford, Ariz.; Memphis (Tenn.) Hospital Medical College, 1894; past president and secretary of the Graham County Medical Society; aged 75; attending physician to the Morris-Squibb Hospital, where he died, Dec. 18, 1941.

Samuel Taylor Barton, Canastota, N. Y.; Kentucky School of Medicine, Louisville, 1893; member of the Medical Society of the State of New York; aged 78; died, Dec. 17, 1941, in the Canastota Memorial Hospital of uremia and diabetes mellitus.

Joseph Everett Nobles @ Greenville, N. C.; Jefferson Medical College of Philadelphia, 1899; past president of the Pitt County Medical Society; for many years physician for the East Carolina Teachers College; aged 66; died, Dec. 13, 1941.

George M. Case @ Elmira, N. Y.; Jefferson Medical College of Philadelphia, 1884; consultant at the Arnot-Ogden Memorial Hospital, St. Joseph's Hospital and the Elmira Reformatory; aged 80; died, Dec. 13, 1941, in Oakland, Calif.

Leander Hugh Conley, Gas City, Ind.; University of Wooster Medical Department, Cleveland, 1883; member of the Indiana State Medical Association; formerly mayor and member of the school board; aged 84; died, Dec. 8, 1941.

Le Roy Downey Howard @ Fairmont, W. Va.; Jefferson Medical College of Philadelphia, 1906; fellow of the American College of Surgeons; on the staff of the Cook Hospital; aged 59; died, Dec. 3, 1941, of coronary thrombosis.

Walter Albert Johnson, Antioch, Calif.; Stanford University School of Medicine, San Francisco, 1932; member of the California Medical Association; aged 35; died, Dec. 9, 1941, in the California Sanatorium, Belmont.

Edgar Woods Jr., Williamsburg, Va.; University of Virginia Department of Medicine, Charlottesville, 1885; at one time a medical missionary in China; aged 82; died, Nov. 5, 1941, of cardiovascular renal disease.

Paul Milton Huddleston @ Huntington, W. Va.; Tulane University of Louisiana School of Medicine, New Orleans, 1936; director of the county school health program; aged 31; died, Dec. 7, 1941, of pneumonia.

George Bernard O'Connell, Lewiston, Maine; University of Vermont College of Medicine, Burlington, 1904; member of the Maine Medical Association; aged 63; died, Dec. 1, 1941, in St. Mary's General Hospital.

William Grady Smith, Wendell, N. C.; Medical College of Virginia, Richmond, 1925; member of the Medical Society of the State of North Carolina; aged 43; died, Dec. 11, 1941, in the Rex Hospital, Raleigh.

Harris Ainsworth Jacobson, Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1910; physician for the draft board; aged 54; died, Dec. 22, 1941.

J. Park Neal, Kansas City, Mo.; University Medical College of Kansas City, 1907; member of the Missouri State Medical Association; on the staff of St. Joseph Hospital; aged 67; died in December 1941.

Arthur Francis Manning, Waltham, Mass.; Harvard Medical School, Boston, 1928; member of the Massachusetts Medical Society; on the staff of the Waltham Hospital; aged 39; died, Dec. 12, 1941.

Gilbert M. La Salle, Wabash, Ind.; Hahnemann Medical College and Hospital, Chicago, 1895; member of the Indiana State Medical Association; aged 71; died, Dec. 11, 1941, of cerebral hemorrhage.

Thomas J. Edge, Graham, Ky.; Louisville and Hospital Medical College, 1908; member of the Kentucky State Medical Association; aged 60; died, Dec. 10, 1941, in Louisville of coronary occlusion.

Walter English Baker, Arden, N. C.; Chattanooga (Tenn.) Medical College, 1908; member of the Medical Society of the State of North Carolina; formerly county coroner; aged 67; died, Dec. 7, 1941.

Charles Francis McClure, Berlin Heights, Ohio; University of Pennsylvania Department of Medicine, Philadelphia, 1899; aged 69; died, Dec. 8, 1941, in the Cleveland Clinic Hospital.

David Frazer Gurd, Montreal, Que., Canada; McGill University Faculty of Medicine, Montreal, Que., Canada, 1879; L.R.C.P., London, England, 1879; aged 90; died, Dec. 7, 1941.

Isaac W. Davenport, Sheridan, Ind.; Medical College of Indiana, Indianapolis, 1881; member of the Indiana State Medical Association; aged 83; died, Dec. 4, 1941.

James William Robinson, Winslow, Wash.; State University of Iowa College of Medicine, Iowa City, 1897; aged 75; died, Nov. 17, 1941, of arteriosclerosis.

Rowland McNair Lancaster, Rural Hall, N. C.; North Carolina Medical College, Charlotte, 1914; served during the World War; aged 55; died, Dec. 4, 1941.

John Crawford Burkhalter, Titus, Ala.; Vanderbilt University School of Medicine, Nashville, Tenn., 1892; aged 72; died, Dec. 11, 1941, of coronary occlusion.

Edward H. Brandt, Warrenton, Mo.; St. Louis Medical College, 1888; aged 75; died, Dec. 11, 1941, in the Barnes Hospital, St. Louis, of cerebral embolism.

Osip Raphael Lourie @ Boston; University of St. Vladimir Faculty of Medicine, Kiev, Russia, 1896; aged 68; died, Oct. 27, 1941, of coronary thrombosis.

Archibald H. Crouch, Forbus, Tenn. (licensed in Tennessee in 1909); member of the Tennessee State Medical Association; aged 69; died, Dec. 1, 1941.

John Owen Campbell, Lebanon, Tenn.; Vanderbilt University School of Medicine, Nashville, 1878; aged 85; died, Dec. 5, 1941, of heart disease.

Walter Francis Feely @ Brooklyn; Columbia University College of Physicians and Surgeons, New York, 1928; aged 38; died, Dec. 3, 1941.

Henry Flowers, Brookhaven, Miss.; Medical Department of Tulane University of Louisiana, New Orleans, 1891; aged 82; died, Dec. 7, 1941.

Lewis Joel Isaacs @ Chicago; College of Physicians and Surgeons of Chicago, 1894; aged 68; died, Dec. 14, 1941, of heart disease.

Anthony Hector Desloges, Montreal, Que., Canada; Laval University Faculty of Medicine, Quebec, 1897; aged 67; died, Dec. 3, 1941.

William Thomas Middlebrooks, Panama City, Fla.; Medical College of Alabama, Mobile, 1886; aged 78; died, Dec. 4, 1941.

John Francis Sullivan, San Francisco; University of California Medical Department, San Francisco, 1900; aged 66; died, Dec. 4, 1941.

Samuel Hirsch @ La Salle, Ill.; Jenner Medical College, Chicago, 1898; aged 78; died, Dec. 14, 1941, in St. Mary's Hospital.

Peter Price Denton, Daytona Beach, Fla.; Medico-Chirurgical College of Philadelphia, 1904; aged 75; died, Dec. 6, 1941.

Herschel G. Pugh, Armstrongs Mills, Ohio; Starling Medical College, Columbus, 1900; aged 76; died, Dec. 2, 1941.

Alexander Marion Moore, Athens, Ga.; Leonard Medical School, Raleigh, N. C., 1913; aged 56; died in December 1941.

Louise Josephine Pitcher, Half Moon Bay, Calif.; Cooper Medical College, San Francisco, 1903; died, Nov. 2, 1941.

Alexander Dawson, Atlanta, Ga.; Southern Medical College, Atlanta, 1891; aged 76; died, Dec. 2, 1941.

Clinton Orlando Fuller, Paradise, Calif.; Milwaukee Medical College, 1901; aged 68; died, Dec. 5, 1941.

John R. Keathley, Griffithville, Ark. (licensed in Arkansas in 1903); aged 77; died, Dec. 7, 1941.

Bureau of Investigation

CEASE AND DESIST ORDERS

Abstracts of Certain Federal Trade Commission Releases

The work of the Federal Trade Commission, in helping to protect the public against misrepresentation or fraud in the medical as well as other fields, has been greatly extended by the provisions of the Wheeler-Lea Amendment to the Federal Trade Commission Act. The Food, Drug and Cosmetic Act of 1938 added to the Food and Drug Administration's control of the advertising claims and statements made on the labels of medicines or on the carton or in the accompanying leaflet, whereas what might be termed collateral advertising, that which appears in circulars, newspapers and magazines and over the air, comes more actively under the purview of the Federal Trade Commission, by virtue of the Wheeler-Lea Amendment.

THE JOURNAL has at various times commented on the activities of the Federal Trade Commission in this connection, even before the Wheeler-Lea Amendment gave it its added rights. In some cases the Commission may accept from the person or concern involved a stipulation that the objectionable practices or claims cited will be discontinued. In other cases the Commission issues what is known as a Cease and Desist Order, in which the individual, manufacturer or distributor cited is ordered to cease and desist from practices which have been declared objectionable. In some cases the claims cited have been discontinued by the firms several months (or even longer) before the issuance of the order. Abstracts of some of the orders issued in 1941 follow.

Anti-Drink—Charging that this is not a cure remedy or competent treatment for alcoholism or the liquor habit and that its use will not eradicate the desire for alcoholic stimulants and that it is not harmless but may result in inflammation of the stomach and intestinal tract and disturbances of the heart and nervous system, the Federal Trade Commission in March 1941 ordered that these misrepresentations be discontinued in the advertising. The defendants in the case were Victoria Chemical Company, Schwarz Druggists, Inc., and Schwarz Drug Stores, Inc., all of Newark, N. J., Schwarz Drug Company, Bloomfield, N. J., Hiram Schwarz, Inc., White Plains, N. Y., and a number of Schwarz's, with an Oscar Katz and a Jacob Eisen, all officers of these firms.

Ardanol, Chloro-Zol and Germ-I-Tabs—These were put out by the American Drug and Chemical Company, Minneapolis, which was ordered in March 1941 by the Federal Trade Commission to desist from advertising that "Ardanol" is a cure or remedy for sterility in either sex, or will restore or beneficially affect fertility, or possesses any value as a preventive of abortion, that "Chloro-Zol" and "Germ-I-Tabs" have any value in feminine hygiene other than as douches, or that Chloro-Zol is a competent treatment for bromidrosis, tetter, Cuban itch and other cutaneous disorders. Incidentally, back in 1931 the label of Chloro-Zol was declared to bear fraudulent claims in violation of the Pure Food and Drugs Act.

BQR (Beeman's Quick Relief)—The Federal Trade Commission found that this is a laxative with mild analgesic properties and has no curative action on the underlying factors that cause colds. Accordingly, in March 1941 it ordered Beeman's Laboratory, Inc., Atlanta, Ga., and two of its officers and a director to cease representing that the product is a cure or remedy for colds or will prevent these or cold infections, or that it will have any effect on colds in excess of what a laxative and mild analgesic will do. Back in July 1937 this company had signed a stipulation with the Commission, promising to discontinue misrepresentations for BQR as an alleged cure for colds, coughs, asthma and influenza.

Breatheasy—The Pascal Company, Inc., of Seattle was ordered by the Federal Trade Commission in April 1941 to cease representing this product as a cure, remedy or competent treatment for chronic bronchitis, asthma or hives and other cutaneous disorders, heart trouble, gastric ulcers, neuralgia, neuritis or inflammations in the head, throat and lungs. The concern was also forbidden to run advertisements that fail to reveal that the stuff cannot be safely used by persons having high blood pressure, toxic goiter, diabetes or heart trouble. A somewhat similar order was issued by the Commission against the Pascal concern in September 1937.

Certane Products—These preparations, put out by Rosemarie Lewis, trading as the Certane Company, Los Angeles, consisted of an ointment, a cream, an antiseptic powder, a douche powder and cones, all sold for feminine hygiene, in connection with appliances known as "Douche Shields," "Apphetors," "Dix Caps" and "Dix Domes." The advertising represented that if used as directed these products would constitute safe and effective preventives against conception and pregnancy and that they prevent disease and consist in whole or in part of ingredients effective in preserving health and youth to wives and mothers. The Federal Trade Commission found that the preparations and appliances would not accomplish these results and that, in fact, serious injury might result from the use of the Douche Shields under certain conditions. In March 1941 the Commission ordered Miss Lewis to discontinue the misrepresentations.

Claro Hair Remover—The Claro Laboratories, Inc., South Bend, Ind., was ordered by the Federal Trade Commission in March 1941 to cease representing that this product constitutes a safe or nonirritating means of removing superfluous hair or will permanently remove such hair or retard its growth. The Commission found that because of the bromium sulfide and potassium hydroxide in the product its use would dissolve only that part of the hair above the skin and would not affect the root or retard hair growth, that it is not safe or nonirritating and in fact, is likely to cause severe dermatitis and chemical burns.

Corn-Go and Liquid Corn-Go—In January 1941 Frank Spors, trading as Spors Company and as Quality Products Company, Le Center, Minn., was ordered by the Federal Trade Commission to discontinue advertisements representing that these products will remove bunions prevent recurrence of corns or calluses or have any other effect on them than temporary removal.

D D D Prescription—This has for years been put out as an alleged remedy for eczema by the D D D Corporation, Batavia, Ill. In May 1941 the Federal Trade Commission ordered the concern to cease representing in its advertisements that the product is a cure or remedy for eczema, pimples or hives or has any value in treating these ailments or cutaneous disorders caused by internal or systemic conditions in excess of affording temporary relief from the symptoms of itching, that it has any effect on cutaneous blotches or rashes when due to systemic or constitutional conditions, or athlete's foot, insect bites or ivy and oak poisoning beyond offering temporary alleviation.

Dr. Blanchard's Regulator—This product, also known as "Dr. Blanchard's Female Compound and Regulator" and "Dr. Jane Blanchard's Compound Regulator," is put out by one Jane Blanchard Geary, trading as Dr. Jane Blanchard, Pittsburgh. In April 1941 Jane Blanchard Geary was ordered by the Federal Trade Commission to discontinue advertisements which represent that her nostrum is a competent regulator of conditions peculiar to women, possesses any value in the treatment of menstrual disorders or is a tonic or a blood purifier or is harmless. She also was ordered to run no advertisements that fail to reveal that her "Regulator" may cause colitis or other serious consequences.

Ethel Bellamy Eyelash Luxuriant—This was the subject of an order issued by the Federal Trade Commission in May 1941 against Ethel Bellamy, Inc., Nutley, N. J., to cease representing that this preparation has any therapeutic value in the treatment of granulated eyelids, that it promotes eyelash growth, supplies pigment to the eyelashes or darkens them permanently or in any way affects eyelash color, except temporarily through its dyeing properties.

Gland Estemeter—This device is put out by the Gland Estemeter Corporation of Chicago, which has for its president one William Estep, who has pretended that the thing can be used for diagnosing certain glandular diseases. Estep's fakery was dealt with at length in this department of THE JOURNAL Jan. 21, 1939, page 260. In June 1941 the Federal Trade Commission reported that its findings were that the Estemeter is incapable of detecting or disclosing improper or abnormal function of the glands and possesses no value in diagnosing diseases or conditions of the body. Estep's claims notwithstanding. The Commission, therefore, ordered Estep and his concern to cease representing in the advertising that all ailments or diseases are caused by improper or abnormal functioning of glands, that the respondents' device detects such improper functioning, indicates vitamin deficiencies, discloses whether the condition of the body is acid or alkaline, shows the condition of the blood with respect to energy or activity, analyzes or reveals impairments of the mental processes, and that this device possesses any value in the diagnosis of any ailment or condition of the body.

Gly-Cas—Medora Whitney, trading as the Gly Cas Medicine Company, and the concern's manager, Robert B. Whitney, Muncie, Ind., were ordered by the Federal Trade Commission in May 1941 to cease and desist from certain advertising misrepresentations. Among these were that the product is a cure or remedy for constipation or affects the condition in any way other than by the temporary relief caused by a partial evacuation of the intestinal tract, that Gly Cas is a cure or competent treatment for indigestion, bloated or sour stomach, pains of rheumatism or neuritis, kidney disorders, sleeplessness or soreness of muscles, limbs or joints when such conditions are due to causes other than constipation. Back in 1932 the Food and Drug Administration declared that the Gly Cas label bore fraudulent claims in violation of the Pure Food and Drugs Act. The case was abstracted in this department of THE JOURNAL Aug. 26, 1933, page 725.

Helene Curtis Duchess Machineless Oil Wave, Machineless DII Solution and Machineless Pads—The National Mineral Company, trading as Helene Curtis Industries, Chicago, was ordered by the Federal Trade Commission in March 1941 to discontinue advertisements which represent that the cosmetic oil contains properties that will supply nourishment or strength to the hair, cause hair to grow or nourish or invigorate the hair roots or shaft, that it is the original machineless oil wave or that the cosmetic pad contains a thermoelectric device or will control or regulate heat or will do more than indicate temperature changes.

Hyral—This was put out by the Hyral Distributing Company, Waller G. Clark and Norma A. Dodge of Fort Worth, Texas. In April 1941 the Federal Trade Commission ordered them to cease representing that their product is a new discovery, has germicidal properties, is a cure or remedy for bleeding gums or other mouth disorders beyond its action as a mild antiseptic, that it is a cure or remedy for trench mouth in excess of temporarily inhibiting the growth of the bacteria causing trench mouth, that it has any value in the treatment of pyorrhea or ill made gums or that it, or healthy, prevent loss of teeth, remove tobacco stains or tartar from teeth or affect unpleasant breath odors except by temporarily removing them.

J R—This was advertised by J R Olney Sr and J R Olney Jr, trading as J R Pharmaceutical Company, Chester, Pa. In June 1941 the Federal Trade Commission ordered these persons to discontinue certain misrepresentations in their advertising, such as that the product is in all cases a cure or remedy for athlete's foot, affords instant relief from athlete's foot, itching toes, ringworm or raw, inflamed feet in excess of temporarily relieving the symptoms of such conditions, is endorsed by leading health institutions or is the only known treatment of its kind. The order also prohibited advertisements which contain the statement "Athlete's foot fungi killed in less than three minutes in laboratory test," or which otherwise represent that the preparation will, in all cases, kill or destroy the fungi causing athlete's foot.

Menstruaid Nos 1, 2, 3, 4 and 5—A J. Hartig, trading as Hartig Drug Company and H K Pharmaceutical Laboratories, Dubuque, Iowa, put out these nostrums. In May 1941 the Federal Trade Commission ordered him to cease issuing advertisements representing that his products constitute a competent treatment for delayed menstruation or that they are scientific, safe and guaranteed. Hartig also was ordered to issue no advertisements that fail to reveal that the use of these products may cause gastro intestinal disturbances and other serious conditions.

Mi-Vit-Ine, Vi-Min-Ex and Muriel Joan Beautifier—Exaggerations in the advertising of these came under the Federal Trade Commission's ban in April 1941 when it ordered Fink & Company, Inc., of New York to cease and desist from certain misrepresentations. Among these were that Mi Vit Ine is a cure or competent treatment for lowered vigor and vitality, colitis or stomach or nervous disorders, that it is a dietary corrective or is composed of a different kind of wheat germ, or that it has any value in treating alcoholism in excess of stimulating the appetite which may have been affected by reason of overindulgence, that Vi Min Ex is a competent treatment for colds, constipation, digestive disorders, neuritis, anemia and some other things or will supply all the minerals and vitamins required by the body, and that the Muriel Joan Beautifier will beautify or transform the face banish pimples, blackheads and other cutaneous blemishes or have any other permanent effect on kindred conditions.

Mrs Bee Femo Caps—In an order issued by the Federal Trade Commission in February 1941, one Carl D Bates, trading as Simmons Cut Rate Drug Store, Cinnandigua N. Y., was forbidden to advertise in the future that this product, also known as "Femo Caps" and "Bee Caps," is a safe and competent treatment for delayed menstruation. The order also prohibits issuance of any advertising which would fail to reveal that the product might cause gastrointestinal disturbances and other serious conditions. Similar orders were issued in March 1941 against Erie Laboratories, Inc., also trading as Mack Pharmaceutical Company, and Allied Pharmaceutical Company, Cleveland, in April 1941 against Sherry's Cut Rate Drug Company, Inc., Bluefield, W Va., and in May 1941 against the Capital Drug Company, Roanoke, Va.

Natural Mineral Extract—In May 1941 the Federal Trade Commission ordered the Colonial Drug Company of Tulsa, Okla., and M A Younkman, its president, trading also as Colonial Sales Company, to cease and desist from certain misrepresentations in the advertising of this product. Among these were that the thing is a cure or remedy for or possesses therapeutic value in the treatment of eczema, acne, athlete's foot, rheumatism and some twenty five other ailments, that it possesses germicidal, antiseptic or astringent properties or has value as a tonic or a blood purifier or as a treatment for women's ailments or ill nourished, backward or defective children.

Neo-Vim (Neo-Vem)—These are names variously given to a preparation put out by the Neo-Vim Company, Columbus, Ohio. In June 1941 this concern was ordered by the Federal Trade Commission to cease representing that the product is a tonic, that its use will supply increased energy or vitality, stimulate the appetite or flow of gastric juices, that it will increase the quantity or improve the quality of the blood and that it constitutes an effective treatment for indigestion or has any therapeutic value other than that of an ordinary laxative.

New Twin-Are Sun Lamp—This was claimed by the Health Ray Manufacturing Company, Inc., Deep River, Conn., to provide "4 minutes light equivalent to one hour of sunshine" to be safe and suitable for home use by women for treating diseases without the supervision of a physician, to help build strong bones and teeth, tone up the system, stimulate the glands, improve health and constitute a cure or remedy for athlete's foot, acne, pimples and surface eruptions of the skin. In March 1941 the Federal Trade Commission ordered the Health Ray concern to discontinue these misrepresentations.

Omega Home Use Portable Machine and Mahler Electrolysis Apparatus—These devices also known as "Omega Method" and "Mahler Method" are promoted respectively by the Omega Manufacturing Company, Inc., (also called Omega Electrolysis Institute) New York, and the D J. Mahler Company, Inc., East Providence, R I. Both devices have been advertised to the public for the self treatment of superfluous hair. In June 1941 the Federal Trade Commission ordered the Omega concern to cease representing that its device is painless, pleasant, quick or easy to use and will have no ill effects on the body. Further, it ordered the Mahler concern to cease representing that its device can be operated with ordinary skill and care. Under their respective orders these concerns were further directed to cease disseminating advertisements which fail to reveal that the use of their devices by persons not trained in the technique of removing superfluous hair from the body by electrolysis may result in permanent disfigurement or cause infections or irreparable injury to health and that these mechanisms should not be used to remove hair from cancerous or syphilitic lesions, pigmented moles or other areas showing local pathologic conditions. Each of the companies had previously been restrained by U S district courts on petition of the Commission from disseminating certain advertisements of their devices pending final disposition of the Commission's case against them. Incidentally the Com-

mission in July 1938, had issued an earlier order against the Mahler firm, directing it to cease representing that its electrolysis device can be used safely by inexperienced operators for the removal of superfluous hair, dark freckles or other cutaneous blemishes.

Petalskin Cosmetics—These are put out by Petalskin Toiletries, Inc., New York, which concern in May 1941 was ordered by the Federal Trade Commission to discontinue certain advertising misrepresentations. Among these were that "Petalskin Face Cream" penetrates deeply into the pores or cleanses the pores any deeper than their external openings, that the product furnishes nourishment to the skin or supplies "Vitamin F," or has any value in restoring the skin, that "Petalskin Face Tonic" will close or refine the pores of the skin, that "Petalskin Cream Pastelle" will refine or close the pores, correct or remove the cause of enlarged pores or have any effect thereon in excess of removing superficial dirt accumulations, that "Petalskin Face Powder" will not clog the pore openings, or that "Petalskin Hand Cream" will penetrate the skin or counteract aging of the skin.

Phalene and Burtone—These were put out by a J H Camp and Drug Profits Inc., Ravenswood, W Va. In March 1941 the Federal Trade Commission ordered the concern to discontinue certain misrepresentations in its advertising, such as that "Phalene" is a liver tonic or is of benefit in preventing premature aging or in removing poisons from the system beyond what an ordinary laxative can do, or that it has any value in treating sick headache, nauseated stomach, aching muscles and joints, run down condition or other disorders in excess of what its laxative action can do. The company further was ordered to cease representing, among other things, that "Burtone" would be of any benefit in bilious attacks, stomach nausea, indigestion or exhaustion beyond giving temporary relief when such conditions are due to constipation.

Princess Pat Cosmetics—The Federal Trade Commission in May 1941 ordered Gordon Gordon, Ltd., and its selling agent, Princess Pat, Ltd., Chicago, to cease and desist from making certain misrepresentations in the advertising of these products. Among these were that face powders containingorris root cause pores to clog, irritate the skin and cause roughness, that "Princess Pat Powder" is nonallergic to all persons, will smooth the skin, make it soft or pliant or prevent coarse pores or blackheads, that the concern's "Muscle Oil" and "Princess Pat Irradiated Muscle Oil" will prevent crows feet, wrinkles or sagging facial muscles or penetrate beneath the skin surface and beneficially affect underlying facial muscles, that "Skin Cleanser" will penetrate beneath the surface or prevent coarse pores, pimples, blackheads or rough skin texture, and that "Skin Food Cream" or "Anti Wrinkle Cream" will nourish or feed the skin or act as a tonic for the underlying nerves or smooth out or prevent underlying wrinkles. The word "food" also was to be eliminated from the name of any Princess Pat product by the terms of the order.

Re Duce-Oids—That this must no longer be represented in advertisements as a safe or effective treatment for obesity was the gist of an order that the Federal Trade Commission issued in May 1941 against the American Medicinal Products, Inc., Los Angeles, and Ernest G Rurup, its president and directing manager. The order also provided that the advertisements must not fail to reveal that the product should be used only under competent medical supervision, as otherwise it might result in serious and irreparable injury to health, or that the product is definitely harmful if used by persons having diabetes, goiter, tuberculosis, arteriosclerosis or coronary diseases, and that its use over a long period might cause the breaking down of muscular and other tissues, as well as fat tissues, causing nervousness, irritability and increased heart rate, with possible irreparable injury to health even to a normal individual. Re Duce-Oids was dealt with at considerable length in this department of THE JOURNAL May 1, 1937, page 1357.

Ru-Ex—In March 1941 the Federal Trade Commission ordered the Ru-Ex Company of St Paul to cease representing that this nostrum is in all cases safe or harmless and to discontinue any advertising which fails to reveal that the product should not be used by persons having tuberculosis or goiter. The order provides that such advertising need contain only a statement that the preparation should be used only as directed on its label when the label warns that the stuff should not be used by those having tuberculosis or goiter. The Commission pointed out that the product, advertised as a remedy for rheumatism, arthritis and neuritis contains potassium iodide in a quantity sufficient to cause injury to health in some instances if used under conditions prescribed in the advertisements or conditions customary or usual.

Thermo-Magnetic Cushion—The Chicago Thermo-Magnetic Cushion Company and its president, A Mercer Parker, were ordered in March 1941 by the Federal Trade Commission to cease and desist from certain misrepresentations in the sale of this device. Among these were that the thing constitutes a cure or remedy for constipation, colds, rheumatism, lumbago sciatica, menstrual and nervous disorders and some other things, or that it has any value in treating such conditions beyond affording temporary relief from the pains accompanying such conditions when localized in an area affected by heat from such device. The respondents also were ordered to cease representing that the use of the "Cushion" will revitalize the human system. This device was declared fraudulent by the Post Office Department in December 1938 and debarred from the mails. The case was discussed at some length in THE JOURNAL Sept 9, 1939, page 1051.

Uvutrin—The John J Fulton Company of San Francisco distributor, was ordered by the Federal Trade Commission in June 1941 to cease representing that this product has substantial therapeutic value in the treatment of diabetes mellitus and that when used with a diet recommended by the company it substantially increases the efficiency of the diet as a treatment for diabetes. The Commission's findings were that the product does not have the represented efficacy in this disease as it does not deal with the causes and its use may be definitely harmful to a diabetic person in giving him a false sense of security and thus causing him to delay seeking scientific treatment. The findings further emphasized that the only recognized treatment for diabetes is diet and insulin, adjusted properly, to meet the needs of each patient.

Correspondence

SENSITIVITY TO WAR GASES

To the Editor:—I read with keen interest a communication to THE JOURNAL, Nov. 29, 1941, page 1879, by Frank B. Queen, M.D., Major, M. C., U. S. Army, and Tom Stander, M.D., Major, M. C., U. S. Army, in which they report a case of severe generalized hypersensitivity to tear gas (CN) considered to be idiopathic. "Of particular interest in the case is the fact that once before the patient had, on transient exposure by passing through a cloud of tear gas during a course of instruction while in the National Guard, experienced itching of the skin which, though remembered seventeen years after the event, was not incapacitating."

Here at Edgewood Arsenal, the center of the Chemical Warfare Service, we have observed that all persons are sensitive to chemical agents when exposed to their effect for the first time. A certain degree of individual variation in sensitivity does occur (as shown by cutaneous tests) regardless of race or color.

It has also been our experience that persons repeatedly exposed to chemical agents such as mustard gas (HS) and, more particularly, tear gas (CN)—for example, plant employees—may in some cases acquire a hypersensitivity which is probably an allergic manifestation. In no case, however, have we noted as severe a general and cutaneous reaction as that experienced by Stander.

EDWARD F. LEWISON, M.D.,
Captain, M. C., U. S. Army,
Edgewood Arsenal, Md.

ACUTE MYOCARDIAL INFARCTION

To the Editor:—The article by Leroy and Snider (THE JOURNAL, Dec. 13, 1941, p. 2019) offers convincing experimental proof that ventricular fibrillation is frequently the cause of sudden unexpected death in dogs with coronary thrombosis and myocardial infarction. However, I feel it is not entirely just to develop the therapeutic regimen they have suggested for the treatment of acute myocardial infarction in man.

Some patients with myocardial infarction die of cardiac standstill rather than ventricular fibrillation (Grieco, E. H., and Schwartz, S. P.: *Ann. Heart J.* 16:595 [Nov.] 1938). There are a number of additional reasons why I think the routine intravenous administration of theophylline with ethylene diamine (aminophylline) and atropine is inadvisable.

The value of theophylline with ethylene diamine or the other so-called coronary vasodilators in the treatment of coronary artery disease is still a very debatable topic. Furthermore, ventricular fibrillation may occur on the fourteenth day following an acute myocardial infarction as well as on the first or second day, so that the suggested treatment would have to be given for that length of time. I believe a patient with an acute myocardial infarct should have as little intravenous medication as possible. An intravenous injection is not an entirely innocuous procedure in a patient with severe myocardial disease and should be avoided wherever possible. Dr. Harold Goldburgh and I have seen at least 2 cases in which we believe sudden unexpected death was due to the intravenous administration of theophylline with ethylene diamine.

One other objection can be raised to this therapy. The authors state that "if the same ratio observed in dogs should hold for human beings, one of three will die instead of three of four" with this mode of treatment. The various published statistics on the mortality of acute myocardial infarction present figures from 8 to 50 per cent. Most of the recent data give an average mortality for all attacks of about 35 per cent. In

work now in progress my associates and I have found similar mortality rates. If one out of three is the average mortality in human beings (and Masters has given a death rate as low as 8 per cent for initial attacks) the plan of therapy given by Leroy and Snider would offer little improvement over our present death rate.

SAMUEL BAER, M.D., Philadelphia.

FALLING DROP METHOD FOR SPECIFIC GRAVITY

To the Editor:—In recent years much interest has developed in the clinical applications of the falling drop method for specific gravity, the chief of which were first pointed out by us in THE JOURNAL, Jan. 8, 1927, page 91. Their usefulness has been recognized in large measure because of the notable studies of shock by Dr. John Scudder.

Clinical interest in the densimetric method has led to the appearance in the literature of a considerable number of so-called "improvements." Modifications of the method, deriving from various sources, are leading to its abuse by the employment of procedures which detract from its sensitivity.

Alluring suggestions, such as "elimination of standards and nomograms," militate against the accuracy of the method. Standard drops of pure potassium sulfate solutions are of constant composition and eliminate the vagaries due to the use of oils as the medium through which the drops fall. Vagaries occur not only because of the variability of all such oils under different conditions of temperature but also because these oils themselves, no matter how "standardized," change their physical properties gradually by such unavoidable factors as evaporation. We went through this immature procedure ourselves, as is shown by our preliminary paper (Blood Specific Gravity: Its Significance and a New Method for Its Determination, *Am. J. Physiol.* 69:654 [Aug.] 1924). Retrogression can hardly be considered an improvement.

Tables of questionable accuracy have appeared to replace the alignment chart. Allegedly simpler, such tables also require the application of a formula. Of the published tables at least one is grossly inaccurate.

For those who object to the use of an alignment chart we suggest the use of a single simple formula, as follows:
$$\text{Log. } Y = 3.9155 + 0.00267 T - (1.2953 + 0.0054 T) \log. X$$
where X = seconds, T = °C and Y = required density difference.

Besides covering all possible determinations by the alignment chart, this formula can be used for drops which require longer than one hundred seconds to fall.

As other examples of false "improvement" may be cited reduction in the length of the drop fall, which decreases sensitivity in proportion to the amount of the reduction; also the use of oils exhibiting viscosity above that of xylene and brombenzene mixtures tends to detract from sensitivity.

Editors accepting alleged "improvements" of methods should, where possible, protect themselves against acceptance of inferior and not altogether harmless material by consulting the original authors. At the side of the "patent medicine racket" and "quack physiotherapy" has arisen the "distorted method" racket!

We hope that this warning against imitations of the falling drop method, hitherto best described by those who toiled over its induction (Barbour, H. G., and Hamilton, W. F.: *The Falling Drop Method for Determining Specific Gravity*, *J. Biol. Chem.* 69:625 [Aug.] 1926), will be appreciated by all workers who may have been, or may in future be, misled.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

ANNUAL CONGRESS ON MEDICAL EDUCATION AND LICENSURE
CHICAGO, Feb 16-17, 1942. Council on Medical Education and Hospitals, Sec, Dr. William D. Cutter, 535 North Dearborn Street, Chicago.

NATIONAL BOARD OF MEDICAL EXAMINERS EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and Examining Boards in Specialties were published in THE JOURNAL, January 10, page 165

BOARDS OF MEDICAL EXAMINERS

ALABAMA: Montgomery, June 16-18. Acting Sec, Dr. B. F. Anstun, 519 Dexter Ave., Montgomery.

ARKANSAS: * Medical. Little Rock, June 4-5. Sec, Dr. D. L. Owens, Harrison. Eclectic. Little Rock, June 4-5. Sec, Dr. Clarence H. Young, 1415 Main St., Little Rock.

CONNECTICUT: * Medical. Examination Hartford, March 10-11. Endorsement. Hartford, March 24. Sec to the Board, Dr. Creighton Barker, 258 Church St., New Haven. Homeopathic. Derby, March 10-11. Sec, Dr. Joseph H. Evans, 1488 Chapel St., New Haven.

DELAWARE: Dover, July 14-16. Sec, Medical Council of Delaware, Dr. Joseph S. McDaniel, 229 S. State St., Dover.

FLORIDA: * Jacksonville, June 22-23. Sec, Dr. William M. Rowlett, Box 786, Tampa.

GEORGIA: Atlanta, June. Sec, State Examining Boards, Mr. R. C. Coleman, 111 State Capitol, Atlanta.

ILLINOIS: Chicago, Jan. 20-22. Superintendent of Registration, Mr. Philip M. Harman, Department of Registration and Education, Springfield.

INDIANA: Indianapolis, June 16-18. Sec, Board of Registration and Examination, Dr. J. W. Bowers, 301 State House, Indianapolis.

KANSAS: Kansas City, June 16-17. Sec, Board of Medical Registration and Examination, Dr. J. F. Hassig, 905 N. Seventh St., Kansas City.

MAINE: Portland, March 10-11. Sec, Board of Registration of Medicine, Dr. Adam P. Leighton, 192 State St., Portland.

MASSACHUSETTS: Boston, March 10-13. Sec, Board of Registration in Medicine, Dr. Stephen Rushmore, 413 F State House, Boston.

MICHIGAN: * Ann Arbor and Detroit, June 10-12. Sec, Board of Registration in Medicine, Dr. J. Earl McIntyre, 202-4 Hollister Bldg., Lansing.

MINNESOTA: * Minneapolis, Jan. 20-22. Sec, Dr. Julian T. Du Bois, 230 Lowry Medical Arts Bldg., St. Paul.

MONTANA: Helena, April 7-8. Sec, Dr. Otto G. Klein, First National Bank Bldg., Helena.

NEVADA: Reciprocity. Carson City, February 2. Sec, Dr. Frederick M. Anderson, 215 N. Carson Street, Carson City.

NEW HAMPSHIRE: Concord, March 12-13. Sec, Dr. T. P. Burroughs, Board of Registration in Medicine, State House, Concord.

NEW JERSEY: Trenton, June 16-17. Sec, Dr. Earl S. Hallinger, 28 W. State St., Trenton.

NEW MEXICO: * Santa Fe, April 13-14. Sec, Dr. Le Grand Ward, 135 Sena Plaza, Santa Fe.

NEW YORK: Albany, Buffalo, New York and Syracuse, Jan. 26-29. Chief, Bureau of Professional Examinations, Mr. Herbert J. Hanulton, State Education Department, 315 Education Bldg., Albany.

OREGON: Portland, Jan. 21-23. Exec. Sec, Miss Lorette M. Conlee, 608 Tailing Bldg., Portland.

SOUTH DAKOTA: * Pierre, Jan. 20-21. Dir, Medical Licensure, Dr. J. F. D. Cook, State Board of Health, Pierre.

TEXAS: Galveston, March 23-25. Sec, Dr. T. J. Crowe, 918 20 Texas Bank Bldg., Dallas.

VERMONT: Burlington, Feb. 10-12. Sec, Board of Medical Registration, Dr. F. J. Lawless, Richmond.

WEST VIRGINIA: Charleston, March 2-4. Commissioner, Public Health Council, Dr. C. F. McClintic, State Capitol, Charleston.

WYOMING: Cheyenne, Feb. 2-3. Sec, Dr. M. C. Keith, Capitol Bldg., Cheyenne.

* Basic Science Certificate required

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

COLORADO: Denver, March 10-11. Sec, Dr. Estlier B. Starks, 1459 Ogden St., Denver.

CONNECTICUT: Feb 14. Address State Board of Healing Arts, 1945 Yale Station, New Haven.

DISTRICT OF COLUMBIA: Washington, April 20-21. Sec, Commission on Licensure, Dr. George C. Ruhlman, 6150 E. Municipal Bldg., Washington.

FLORIDA: Gainesville, June 8. Sec, Professor J. F. Conn, John B. Stetson University, De Land.

MICHIGAN: February 13-14. Sec, Miss Flora E. Dube, East Lansing.

NEW MEXICO: Albuquerque, Feb. 2. Sec, Miss Pia Joerges, State Capitol, Santa Fe.

OREGON: Portland, Feb. 14. Applications must be on file not later than Jan. 28. Sec, State Board of Higher Education, Mr. Charles D. Byrne, University of Oregon, Eugene.

RHODE ISLAND: Providence, Feb. 18. Chief, Division of Examiners, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

Nevada Reciprocity Report

The Nevada State Board of Medical Examiners reports 2 physicians licensed to practice medicine by reciprocity on August 4. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad	Reciprocity with
University of Illinois College of Medicine.	(1941)	Illinois
McGill University Faculty of Medicine.	(1940)	California

Colorado October Report

The Colorado State Board of Medical Examiners reports the written examination for medical licensure held at Denver, Oct. 8-10, 1941. The examination covered 8 subjects and included 64 questions. An average of 75 per cent was required to pass. Six candidates were examined, 4 of whom passed and 2 failed. Five physicians were licensed to practice medicine by endorsement. The following schools were represented:

School	PASSED	Year Grad.	Number Passed
University of Colorado School of Medicine	(1940)	1
Rush Medical College.	(1941)	1
University of Tennessee College of Medicine	(1940)	1
Osteopath *		1

School	FAILED	Year Grad.	Number Failed
Osteopaths *		2

School	LICENSED BY ENDORSEMENT	Year Endorsement of Grad.	
Rush Medical College.....		(1937)	Illinois
University of Kansas School of Medicine.....		(1930)	Kansas
University of Nebraska College of Medicine . . .		(1922)	N. B. M. Ex.
Duke University School of Medicine.....		(1938)	N. B. M. Ex.
University of Oklahoma School of Medicine.....		(1938)	Oklahoma

* Examined in medicine and surgery.

* Examined in medicine and surgery.

Washington July Report

The Washington State Board of Medical Examiners reports the examination for medical licensure held at Seattle, July 21-23, 1941. The examination covered 7 subjects and included 70 questions. An average of 60 per cent in each subject was required to pass. Forty candidates were examined, all of whom passed. Thirty-seven physicians were licensed to practice medicine by reciprocity and 9 physicians so licensed on endorsement of credentials of the National Board of Medical Examiners. The following schools were represented:

School	PASSED	Year Grad	Number Passed
College of Medical Evangelists	(1941, 3)	3
Loyola University School of Medicine.	(1941, 3)	3
Northwestern University Medical School.	(1939), (1941)	2
Rush Medical College.	(1937), (1940, 2)	3
University of Chicago, The School of Medicine.	(1939)	1
University of Illinois College of Medicine.	(1940), (1941)	2

MEDICOLEGAL ABSTRACTS

Evidence: Communications Between Workmen's Compensation Claimant and Examining Physician Not Privileged.—Information, the court of appeals, Franklin County, Ohio, holds, obtained by and the diagnosis made by a physician who on the request of the industrial commission examines a claimant for compensation under the Ohio workmen's compensation act to determine if the disability involved is connected with an industrial accident is not privileged under the Ohio statute which makes privileged a communication made to a physician "in that relation, or his advice to his patient." The testimony of such a physician as to his diagnosis of the claimant's condition is admissible in a proceeding to recover compensation instituted by the claimant. For a communication to qualify as privileged under the statute, said the court, it must not only appear that the evidence presented the relation of physician and patient but also that any communication made was "in that relation." In the opinion of the court it could not be said that, where a physician examines a claimant for the purpose of ascertaining conditions determinative of a fact essential to a cause of action, the physician has received a communication in the relation of physician and patient.—*McMillen v. Industrial Commission of Ohio*, 37 N. E. (2d) 632 (Ohio, 1941).

Medical Practice Acts: Revocation of License to Practice Physiotherapy.—The medical practice act of New York provides for the licensing of both physiotherapists and practitioners of medicine. The provisions of the act relating to the revocation, suspension or annulment of licenses, however, refer only to practitioners of medicine. If "a physician has been convicted in a court of competent jurisdiction, either within or without this state, of a crime," disciplinary action is authorized. In 1930 the plaintiff was granted a license to practice physiotherapy in the state of New York; in 1936 the Regents of the University of the State of New York revoked that license on proof that the plaintiff had been convicted of a crime. From such action by the Board of Regents, the plaintiff appealed to the supreme court, special term, Ulster County, New York.

The plaintiff contended that the disciplinary provisions of the medical practice act had no relation to physiotherapists but were applicable only to practitioners of medicine. The evidence showed that the plaintiff had been properly notified of the hearing before the Medical Committee on Grievances and that the same formal procedure required to hear and determine charges of unfitness against a physician was applied to the plaintiff. The supreme court held that, since the Regents were authorized to grant the plaintiff a license, they were likewise authorized, in their supervisory capacity, to revoke that license for proper and sufficient cause. The order revoking the plaintiff's license to practice physiotherapy was accordingly confirmed.—*Swift v. Graves, Commissioner of Education, et al.*, 19 N. Y. S. (2d) 686 (New York, 1940).

Medical Practice Acts: Suspension of License for Use of Quack Methods of Diagnosing.—The defendant had been licensed to practice medicine in the state of Minnesota. After entering into active practice he was twice warned by the state board of medical examiners that some of his conduct was not strictly scientific. At length one of his former patients filed a complaint before the board charging that the defendant conducted himself in a manner unbecoming to persons licensed to practice medicine and that certain methods of diagnosis used by the defendant were improper and unprofessional. On the basis of the evidence presented, the board suspended the defendant's license to practice medicine for a period of five years. From an order of the district court dismissing an appeal from the board's ruling, the defendant appealed to the Supreme Court of Minnesota.

The defendant himself described his method of diagnosis. A piece of wood pulp paper, moistened by the patient's own saliva, was placed on a selected spot on the patient's abdomen and apparently produced some "line on the person's abdomen." Different drugs were then placed in the patient's hand—"left hand for female and right hand for the male." If the drug or medicine which the patient held was the one which would effect a cure, or the one most likely to do so, some reaction, apparent to the defendant, would result from the paper on the patient's abdomen and the line on the patient's abdomen would "go down deeper, three or four finger breadths deeper." In this manner the defendant was able to determine the proper type of medication. He further frankly testified that his method of diagnosis was "fairly dependable" without his having to see or examine the patient. All he needed was the test paper, moistened by the patient's tongue. This paper would be mailed to him, placed on another person's abdomen and different drugs placed in the "subject's" hand. The diagnosis would then be made according to reactions apparent to the defendant. Absentee patients invariably received pills or pellets compounded entirely of sugar and milk. According to the defendant's testimony these pills received their therapeutic potency from "energy" with which he charged them from a machine with a certain "hook-up." There was no attempt by the defendant to justify his habitual methods of diagnosis and treatment on any scientific basis.

The defendant first contended that the proceedings before the board constituted a denial of due process or equal protection of the law because the board acted as both prosecutor and judge. The Supreme Court found that the defendant had been given ample notice of the charges against him and had been heard at great length in his own behalf. Furthermore, the whole proceeding before the board had been subjected to review by the district court. The contention was therefore overruled.

The defendant also contended that he had been denied the privilege of introducing the testimony of three witnesses in his behalf. These witnesses had been present at the hearing but had left prior to its conclusion. The board refused an adjournment in order to take their testimony. The witnesses were all laymen, and the defendant made no offer of proof to show how their testimony would have benefited him, except to indicate that they had been successfully treated. However, the court said that the defendant's diagnostic methods were "so clearly bald quackery, and so much an imposition on his patients, that the testimony of 3 patients with whom he had had good luck would not have helped him." In conclusion the court said that it was impossible to hold for the defendant "until the methods of the aboriginal medicine men, the witch doctor, and voodooism are demonstrated to be superior to those of modern science as applied in the field of medicine. The board of seven competent doctors adhered to the notion that the accomplishments of biochemistry and microscopy, with their diagnostic disclosures (which in many cases go to the point of demonstration) are superior to quackery, ancient and modern." The board's order was therefore affirmed. A petition for a writ of certiorari was denied by the United States Supreme Court.—*Minnesota State Board of Medical Examiners v. Schmidt*, 292 N. W. 255; 61 S. Ct. 135 (Minn., 1940).

Society Proceedings

COMING MEETINGS

Annual Congress on Medical Education and Licensure, Chicago, Feb. 16-17. Dr. William D. Cutter, 535 North Dearborn St., Chicago, Secretary.

American Orthopsychiatric Association, Detroit, Feb. 19-21. Dr. Norville C. LaMar, 149 East 73d St., New York, Secretary.
Central Surgical Association, Chicago, Feb. 27-28. Dr. George M. Curtis, Ohio State University, Columbus, Ohio, Secretary.
Pacific Coast Surgical Association, San Francisco and Del Monte, Calif., Feb. 17-20. Dr. F. L. Reichert, Stanford University Hospital, San Francisco, Secretary.
Society of Surgeons of New Jersey, Trenton, Jan. 23. Dr. Walter B. Mount, 21 Plymouth St., Montclair, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1931 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

- Physical and Chemical Properties of Sputum: I. Factors Determining Variations in Portions from Different Parts of Tracheobronchial Tree. F. P. Basch, P. Holinger and H. G. Poncher, Chicago.—p. 981.
- Incidence and Nature of Fetal Arrhythmias. L. W. Sontag and Helen Newbery, Yellow Springs, Ohio.—p. 991.
- School Health Service and the Private Physician. A. H. Kantrow, New York.—p. 1046.
- Communicable Disease and the School. G. M. Whentley, New York.—p. 1052.
- Rural Communicable Disease Programs. M. R. Kinde, Battle Creek, Mich.—p. 1060.

Stature and Weight of Children.—In determining the average stature and weight of boys aged 9 to 14 years in the United States Meredith finds that boys living in the United States today, white and Negro, are 6 to 8 per cent taller and 12 to 15 per cent heavier than they were half a century ago. White boys of families of the professional and major managerial classes are 3 per cent taller and 6 per cent heavier than those of families of the unskilled and semiskilled classes. Boys in the United States of various ethnic groups in no instance appear to differ in average stature by more than 2 inches (5 cm.). The accessible averages for weight fluctuate so that a reasonable estimate of the maximal difference is precluded. Averages for stature and weight vary but slightly for white boys residing in different parts of the United States.

Intradermal Immunization.—Van Gelder and Fisher compared the intradermal and subcutaneous methods of typhoid vaccination by giving 285 children three injections of typhoid vaccine subcutaneously and 295 three injections intradermally. The vaccine used contained 1,000,000,000 typhoid bacilli in 1 cc. The first group were given 0.5, 1 and 1 cc. of the vaccine. The respective doses for the other group of children who were subdivided into three subgroups were: 0.05, 0.1 and 0.1; 0.05, 0.1 and 0.15, and 0.1, 0.15 and 0.2 cc. Forty-eight of the children who received the typhoid vaccine subcutaneously had some systemic reaction after at least one injection, usually the first. Sore arms were complained of after eighty-six injections and tender regional adenitis after seven. No significant difference in the subsequent agglutinin titer of the blood was observed whether the vaccine was given at intervals of two or three weeks. No somatic, or O, agglutinin appeared in the blood of 103 children; a titer of 20 developed in 5, of 40 in 1, of 80 in 6 and of 160 in 170. The flagellar, or H, agglutinin titer was negative for 1, 320 for 4, 640 for 262 and 1,280 for 18. Only 8 of the 295 children given the vaccine intradermally experienced any systemic mild reaction; most of them were among the subjects of the third subgroup. Somatic, or O, agglutinins were not stimulated to any considerable degree by the intradermal injections, but the three doses given the second subgroup or those given the third subgroup increased the flagellar, or H, agglutinin titers to levels about as high as those obtained by

the subcutaneous method. Despite the fact that O agglutinins are stimulated by the intradermal method, the authors believe that the method is satisfactory, because reactions are practically eliminated and the difference between the agglutinin titers of the two methods does not seem highly significant. The three doses most satisfactory for intradermal injection for subjects weighing 120 (54.5 Kg.) or more pounds are 0.05, 0.1 and 0.15 cc., because the reactions after this dosage are minimal and there is no significant lowering of the subsequent agglutinin titers.

Werner's Syndrome.—Oppenheimer and Kugel discuss the data of the first necropsy of a patient with Werner's syndrome. The observations at necropsy, they say, confirmed the clinical evidence of endocrine stigmatization: atrophy of the testes and the prostate gland, adenomas of the thyroid and adrenal and evidence of hyperactivity of the parathyroid. The pituitary gland showed no abnormalities. They enumerate the following as clinical evidences of parathyroid hyperactivity: generalized and localized osteoporosis, metastatic calcification, transient and recurrent hypercalcemia, abnormal negative calcium balance and increased circulation of the parathyroid secretion.

Idiopathic Hypoproteithrombinemia.—The unexpected finding of a prothrombin deficiency in a white youth of 18 with supposed hemophilia led Rhoads and Fitz-Hugh to study the defects of the coagulability of this patient's blood more carefully. The prothrombin time was definitely prolonged. The diagnosis, during fifteen previous admissions to the hospital, had always been hemophilia. Because of the hypoproteithrombinemia the diagnosis of hemophilia was abandoned and that of idiopathic hypoproteithrombinemia was substituted. Because of the early onset of symptoms, the condition may have been congenital. The family history was negative, and the plasma prothrombin concentration of the patient's mother and brother was normal. The disease differed from typical hemophilia in that clot retraction was poor. None of the tests of hepatic function revealed any evidence of hepatic damage. At necropsy no gross hepatic abnormality was discernible, and the microscopic changes were much less than those found in patients with hypoproteithrombinemia due to hepatic damage. The possibility of a toxic agent which destroyed prothrombin directly seems unlikely, as the patient did not improve with changes in diet and environment.

Neither a disorder of the digestive tract nor failure to absorb vitamin K were factors in the patient's illness. The studies carried out indicate that his coagulation defect was due to a lack of prothrombin and to a qualitative defect in fibrinogen without a quantitative defect.

Guanidine Hydrochloride in Myasthenia Gravis.—On the basis of the results that Dodd and her associates obtained with guanidine hydrochloride in 6 patients with myasthenia gravis and those obtained in 21 cases by other workers the authors conclude that the drug causes temporary improvement in muscular function in most patients with the disease. These patients have an increased tolerance to guanidine. Prolonged medication produces sustained improvement without harmful effects. Generally less of the drug is required after several months of adequate individual medication. Guanidine, unlike prostigmine, does not inhibit the activity of choline esterase. It may play a fundamental part in restoring irritability to cells.

Effect of Alcohol on Vision.—Newman and Fletcher studied the affect that alcohol had on the vision of 35 men and 15 women drivers after they had consumed within fifteen to thirty minutes at least 1 ounce (30 cc.) of whiskey to each 30 pounds (13.6 Kg.) of body weight. Seven tests (for visual acuity, depth perception, distance judgment, lateral fields of vision, eye coordination, glare resistance and glare recovery) were given the subjects prior to their ingestion of the whiskey and again forty-five minutes after its consumption. The alcohol produced changes in all the components of vision tested but not all the components of all the persons tested were affected. Although there was an obvious tendency for persons with higher concentrations of alcohol in their blood (which varied from 58 to 218 mg. per hundred cubic centimeters) to show more changes, particularly major changes, this was far from true in every instance. From the data it is impossible to select any single concentration as a criterion of dangerous intoxication. The figure of 150 mg. per hundred cubic centimeters proposed as *prima facie* evidence of drunkenness by the National Safety Council, would be too high for some subjects and too low for others. In every volunteer with a concentration of more than 115 mg. of alcohol per hundred cubic centimeters of blood there was a significant change in at least one of the tests performed. The greatest number of changes occurred in visual acuity, the smallest in the field of vision.

Eye Disease and Vitamin Deficiency in Trinidad.—Metivier points out that, while frank beriberi and classic pellagra are clinical curiosities in Trinidad, the ocular manifestations of vitamin B deficiency, particularly vitamin B₂, are frequent. As long as attempts are made to designate all vitamin deficiency diseases as pellagra the great morbidity in the colonies due to vitamin deficiencies will not be unearthed and recent advances will have no meaning. The author discusses the closely related syndromes in which ocular changes and visual defects are prominent features of vitamin deficiency in warm climates. "Tropical nutritional amblyopia" is suggested for the disease which results from failure of vitamin B₂ to maintain nutrition of the optic nerve, either directly or through retinal elements. When the nutrition of the cornea suffers from deficiency of vitamin B₂, essential corneal epithelial dystrophy, particularly xerophthalmosis, is the disease that develops in Trinidad. A dry parched skin is seen in patients with ocular disease due to vitamin B₂ deficiency.

Gastric Emptying Time of Old People.—Van Liere and Northup determined, under the fluoroscope, the gastric emptying time of 12 men from 58 to 84 years of age. Ten of the subjects were indigent persons residing in a county infirmary, 1 was a college professor and 1 was a janitor. The average gastric emptying time of the 12 men was one and ninety-four hundredths hours, the extremes ranged from one and thirty-three hundredths to two and seventy-five hundredths hours. The corresponding figures for 59 young adults were two and eight hundredths, one and three hundredths and three and eight hundredths hours. It seems that senescence does not influence gastric emptying.

Roentgenologic Diagnosis of Hepatic Carcinoma.—

According to Schatzki, the roentgen demonstration of a mass in the region of the liver and the lobulation of the diaphragmatic shadow may be produced by metastatic tumors, echinococcus cysts and possibly gumma as well as primary hepatic cancer. Any localized bulge of the diaphragm in a patient with proved cirrhosis of the liver should be taken seriously, particularly if it occurs in an unusual location, and the possibility of a primary hepatic cancer in all such patients should be considered. A combination of cirrhosis of the liver (varices) and a mass in the region of the liver is highly suggestive of a primary hepatic cancer. The combination of cirrhosis (varices) and positive evidence of cancer (i. e., pulmonary metastasis) is less conclusive. However, the presence of all three factors makes the diagnosis of primary hepatic cancer extremely likely. The author reports 4 cases in which a roentgen diagnosis of hepatic carcinoma was made.

Prophylaxis of Pulmonary Embolism.—Fine and Sears state that division of the femoral vein is advisable as a routine prophylactic measure against pulmonary embolism when thrombosis of the deep veins of the lower leg is present or suspected. They do not refer to pulmonary embolism arising from auricular fibrillation or any vascular disorder of the venous system cephalad to the great veins in the pelvis. The value of such prophylaxis can be affirmed only after it has been done in a large series of patients with phlebitis and the incidence of fatal and nonfatal pulmonary embolus has been lowered significantly. The most desirable site for blocking the discharge of an embolus from the deep veins of the lower leg is just below the vena profunda.

Endometriosis.—Meigs believes that the increased frequency of endometriosis, a representation of an abnormal physiology, is due to late marriage and delayed and infrequent childbearing. To prove this contention he compares the incidence of endometriosis among 400 consecutive private patients, most of them fairly well to do, who had abdominal gynecologic operations and 400 patients from the Massachusetts General Hospital. The hospital patients are of the social status that marries early and has children frequently. The more normal functions of this group are reflected in the small incidence of endometriosis. Of the private patients 112, or 28 per cent, showed microscopic evidence of endometriosis, as against 23, or 5.8 per cent, in the Massachusetts General Hospital group. Further study shows that endometriosis is a stigma of infertility, and it is due to uninterrupted menstrual cycles, because of late marriage and infrequent childbearing. It is increasing among women having few children and having them late in life. Early marriage and early and frequent childbearing should be urged.

Pott's Disease.—Harris and Coulthard emphasize three early manifestations of Pott's disease which permit early diagnosis: 1. An analysis of the quality of the pain from which the patient suffers demonstrates that it is of spinal origin, is intensified by movement, weight bearing and jolting and is relieved by rest. 2. Roentgen study reveals a thin intervertebral disk before the characteristic caries of the vertebral bodies is manifest. 3. Aspiration of the focus of infection under roentgen guidance will yield pus from which a positive diagnosis can be made.

Vitamin A Deficiency and the Nervous System.—From their experiments on laboratory animals Wolbach and Bessey predict that acute uncomplicated vitamin A deficiency in infants would produce the same changes: an overgrowth of the central nervous system (in relation to osseous growth) with consequent mechanical injuries to the brain, spinal cord and nerve roots.

Incidence of Occult Adenocarcinoma of Prostate.—Baron and Angrist state that the examination of random sections of the prostate gland in 364 men more than 50 years of age revealed adenocarcinoma in 14.8 per cent; the prostates of 9.9 per cent contained occult adenocarcinoma, and 4.9 per cent of the 364 patients died of extensive prostatic adenocarcinoma with metastasis.

Blood Prothrombin in Newborn.—Ross and Malloy found that newborn infants showing asphyxia have spontaneous hemorrhage more frequently than normal infants. In 3 of 9 such infants spontaneous bleeding developed. The maximal prothrombin time of these 9 infants was between 110 and 300 seconds, with an average of 195 seconds. These high values and the

fact that 3 bled spontaneously may be of some significance. Anoxemia may be a factor in the production of hypoprothrombinemia in this condition. There is no relationship between physiologic jaundice of the newborn and hypoprothrombinemia. Therefore the authors suggest that a prophylactic dose of vitamin K might be of value for premature infants (because of their tendency to traumatic and spontaneous hemorrhage) and in newborn infants with asphyxia. Vitamin K is also indicated in traumatic bleeding, especially intracranial hemorrhage.

Paroxysmal Tachycardia in Childhood.—Baker reports the presence of the classic type of paroxysmal tachycardia in a girl of 16. Clinically the girl's heart was normal, in spite of recurrent attacks of paroxysmal tachycardia for eight years' (since she was 8). The tachycardia conformed to the classic adult type in every respect.

Adolescent Hyperthyroidism.—Black and Webster state that, from September 1932 to September 1940, 747 patients with diffuse or nodular toxic goiters were seen at the New York Hospital and that 26 of them were less than 18. Eighteen of the 26 adolescents were patients of the medical and surgical services; 17 had toxic diffuse goiter and 1 had a toxic nodular goiter. In the group there were 15 girls and 3 boys aged 10 to 17 years at the time the symptoms ensued. In 13, all girls, the onset of symptoms occurred at the 13 and the 14 year age level. The etiologic factors involved include infection (either closely preceding or associated with the appearance of symptoms), psychic trauma, exophthalmic goiter or "goiter trouble" in

parents or close relatives and a combination of the foregoing factors. Only 1 of the patients, a boy, had another associated endocrine disorder; he showed signs of hypogonadism. All but one of the glands that were resected were described by the pathologist as "hyperplastic goiters" with various degrees of involution. The exception was described as an "intermediate adenomatous goiter (fetal adenoma)." The symptoms of this patient were entirely similar to those of the other patients although exophthalmos was not present. Conservative, non-surgical treatment failed to arrest the disease of 5 of 6 patients. After thyroidectomy the growth and the mental development of the children operated on proceeded, in the absence of any recurrence, in an entirely normal manner. Postoperative myxedema of any permanent importance did not occur. However, postoperative recurrences and persistent hyperthyroidism occurred in 3 of the patients who had thyroidectomy. This complication apparently developed irrespective of the mode or the duration of the preoperative or the postoperative management. Therefore thyroidectomy is a therapeutic necessity, and the physician, while fully aware of the risk entailed, has no reasonable alternative but to advise such a procedure.

Amenorrhea and Hypopituitarism.—Ornstein employed estrogens for the treatment of 4 patients (aged 27, 24, 19 and 16 respectively) with hypopituitarism of the Lorain-Lcvi type, with sexual and somatic infantilism. Continuous treatment induced cyclic uterine bleeding associated with changes in the secondary sex characteristics. Parenteral and oral therapy were equally effective. The implantation of pellets of estradiol benzoate complemented by regularly spaced periods of oral administration of progesterone was most effective. When therapy was discontinued or the gonadotropes were used, bleeding ceased and the increased mammary tissue regressed about 25 per cent. Pregnant mare's serum and a combination of chorionic gonadotropin and an anterior pituitary gonadotropic extract were ineffective in inducing bleeding or in maintaining the secondary sex characteristics. The psychologic improvement alone justifies the treatment. Therapy should not be begun before 17, or at least until delayed puberty has been ruled out.

Virus Infections of Central Nervous System.—Casals and Palacios describe a complement fixation test for various virus infections of the central nervous system for which emulsions of infected brain tissue are used. The brain emulsion is frozen, thawed and then centrifuged in an angle head centrifuge at 3,500 revolutions per minute for one hour. The method has proved reliable in experiments with rabies, St Louis encephalitis, Japanese B encephalitis, lymphocytic choriomeningitis, eastern and western equine encephalomyelitis, louping ill and spontaneous encephalomyelitis of mice (Theiler's disease). Complement fixing antibodies in high titer were found in the serums of rabbits, guinea pigs, mice and dogs immunized with rabies virus. Complement fixing antibodies were present in high titer in the serum from 2 persons eight years after an attack of louping ill, from 5 persons two and one-half years after an attack of eastern equine encephalomyelitis and from 2 persons two and one-half years after they had western equine encephalomyelitis. Complement fixing antibodies of St. Louis encephalitis and lymphocytic choriomeningitis have been found soon after infection but not after long periods.

Neutralizing Antibodies After Influenza A.—Horsfall and Rickard determined the neutralizing capacity of the serum from 5 patients with influenza A against three antigenically different strains of influenza A virus and one strain of swine influenza virus. With a single exception all the serum produced almost identical quantities of neutralizing antibodies against each of the virus strains used. Although the serum of the fifth patient had similar concentrations of antibodies against strain 399, the PR8 strain of influenza A virus and the swine influenza virus, only a slight increase in antibodies was demonstrable against the W. S. strain. The increases in neutralizing antibody levels of the serum of the 5 patients after infection were as readily demonstrable when one antigenically different strain of influenza A virus was used as when another one was used. Furthermore, even when the swine influenza virus was used closely similar alterations in antibody levels were encountered. The data of the study indicate that in adults, irrespective of the time which elapses after the onset of influenza A, there is an almost complete lack of strain specificity in the immunologic response that follows.

Influence of Antepartum Diet.—Ebbs and his associates studied the antepartum diets of 380 women with low incomes. A group of 120 women found to be on a poor diet was left as a control, the diet of a group of 90 women on a poor diet was supplemented with milk, eggs, oranges, tomatoes and cheese during the last three or four months of pregnancy and the diet of 170 women on a moderately good antepartum diet was improved by education alone. The mothers on a good or a supplemented diet enjoyed better health, had fewer complications during pregnancy and proved better obstetric risks than those on a poor diet. Miscarriage, stillbirth and premature birth as the result of the pregnancy of the women on poor diets were more frequent, and the incidence of death and of illness among their babies up to the age of 6 months was many times greater.

Poliomyelitis.—In order to add to the available data on the transmission of poliomyelitis Perkins reports its apparent radial spread in 1930 by four rural households in the southwestern corner of Minnesota. There were a total of 166 patients, with involvement ranging from fatal paralysis to involvement which merely produced pain on anterior flexion of the neck. Concerning 53 of the 166 patients investigated a history of exposure within thirty days of illness to another patient, acutely paralyzed or nonparalyzed, was obtained. Among the 878 household members of the 166 patients with paralytic and nonparalytic poliomyelitis 174 had illnesses classified as suggestive (producing systemic symptoms similar to those of patients with a diagnosis of poliomyelitis but with no evidence of involvement of the nervous system). Some additional illnesses may have occurred subsequent to the author's last visit. No one suggestive symptom exceeded 50 per cent, but a total of 82 per cent of the patients had headache, fever, diarrhea and/or vomiting. Headache was always combined with one or more of the suggestive symptoms. There was a similarity in the age distribution among the patients with definite and suggestive illnesses. The rate of attack of definite disease was higher for males than for females in all but the group aged 25 to 49. For the suggestive disease the reverse was true. If it is assumed that the illness of the patients with suggestive disease also was due to the poliomyelitis virus it may be hazarded that, although male patients experience involvement of the nervous system more frequently, female patients suffer a higher subclinical attack rate.

- Description of Home Made Hydraulic Dredge Employed in Malaria Control at Perry, Fla. A. C. Newman.—p. 2127.

Epidemiologic Study of Calcified Pulmonary Lesions.—From the roentgenograms of 279 members of forty-four households Olson and his associates found that a high familial incidence (of 49.4 per cent among the 253 household members of whom adequate roentgenograms were had) of pulmonary calcification existed among these families, who resided in Ross County, Ohio. The selection of households was made through an index person, a pupil, found to have pulmonary calcification in the survey made by Lumsden and Dearing in three Ross County schools. Roentgenologically the calcification produces pulmonary lesions which simulate those of primary tuberculosis. Only 12, or 4.7 per cent, of the 253 household associates had a household

history of contact with tuberculosis. No relationship could be demonstrated between the contact and the pulmonary calcification. The possible etiologic part that *Ascaris* played in the calcification was neither proved nor disproved, as the incidence of parasites in the household members and in samples of soil near their homes was so similar for the persons with and for those without pulmonary calcification that no conclusion could be drawn.

- *Positive Agglutination Tests in Suspected Cases of Weil's Disease. A. Packchianian.—p. 2145.

Agglutination Tests and Weil's Disease.—During the last four years, using the microscopic agglutination test, Packchianian found agglutinins for type I *Leptospira icterohemorrhagiae* in the serum of 40 patients suspected of having Weil's disease. One patient resided in Connecticut, 4 in Louisiana, 9 in Maryland, 2 in Massachusetts, 2 in Michigan, 2 in Missouri, 1 in Nevada, 2 in New Jersey, 5 in New York, 4 in Ohio, 1 in Pennsylvania, 4 in Virginia, 2 in West Virginia and 1 in the District of Columbia. Thirty-six patients were men, 1 was a woman and 3 were children. The occupation or the place of residence of most of the patients was such that contact with wild rats might be expected. Six patients died. Sixty-one samples of blood from 36 patients were retested after storage in the refrigerator at 5 C. for one hundred and sixty-nine to one thousand and seventy-eight days and, with four exceptions, strong agglutination reactions with type I *L. icterohemorrhagiae* were obtained. The agglutination titers approached, or were identical with, the original titers. Blood samples from 20 jaundiced dogs (from Louisiana, Nebraska, New York, Pennsylvania and Virginia) likewise gave strong agglutination reactions in dilutions of 1:30,000 and higher. Virulent strains of *L. icterohemorrhagiae* were isolated from wild rats (*Rattus norvegicus*) captured in Detroit, in New York and in Washington, D. C.

Transanal Approach to Ethmoidal and Sphenoidal Sinuses: Some Further Considerations. J. B. Horgan.—p. 290.

Respiratory Disease and Chest Surgery.—Ormerod assessed the part that disease of the upper respiratory tract had in the condition of 40 patients with bronchiectasis. Eighteen of the patients had no demonstrable lesion in the upper air passages though 3 had had tonsillectomies many years before. The other 22 showed some inflammatory lesion in the nose, the paranasal sinuses, the postnasal space or the pharynx. Fourteen of these 22 had had operations on the nose or the throat. Data show that about 80 per cent of patients with bronchiectasis have some degree of infection of the paranasal sinuses but that disease of the tonsils is of slight etiologic importance. About 20 per cent or more of the patients with pulmonary abscesses had tonsillectomies, and a few had other operations on the upper part of the respiratory tract but sinusitis did not appear responsible for the pulmonary abscesses. The connection between the upper and the lower respiratory tract may be by aspiration, lymph stream, blood stream and direct continuity. The aspiration theory seems to be the most probable. Bronchitis and its sequelae may explain many cases of bronchiectasis though probably not pulmonary abscesses. The foci of disease of the upper respiratory tract should be eliminated before the secondary chronic inflammatory lesions of the lungs are dealt with if a lasting cure is to be obtained and constant reinfection avoided. Sinuses should be drained, polyps removed and severe septal deflections corrected before operation on the chest. In children, with profuse purulent secretion, tonsils and adenoids can be removed with ease and safety after the chest has been treated. However, the nose and throat should be cleared of infected lymphoid tissue before the child leaves the hospital.

*Chronic Pancreatitis, with Hyperfunction of Islands of Langerhans. J. W. Grott.—p. 72.
Clinical Aspects of Diverticulum of Duodenojejunal Flexure. W. Schoen.—p. 90.

Chronic Pancreatitis, with Islet Hyperfunction.—Grott reviews observations on 42 cases of chronic pancreatitis in which hyperinsulinism was indicated by low or flat blood sugar curves after tolerance tests with 50 Gm. of dextrose. The starting point of the diagnosis was the physical exploration of the pancreas by the author's method. The patients often complained of general lassitude, sleepiness, increased nervousness and, in rare cases, symptoms of severe hypoglycemia. The physical examination disclosed hypersensitivity in 46 per cent, trophic changes of the skin in 69.5 per cent, pain sensitivity of the pancreas in 97.6 per cent and enlargement of the pancreas in 28.57 per cent. The diastase of the urine was increased in 40 per cent and renal diabetes existed in 45.2 per cent. The author concludes that chronic pancreatitis with hyperfunction of the islands of Langerhans is not a rarity and demands special treatment. Sugar and sweets must be avoided, because they are too rapidly absorbed and stimulate the islands to hyperfunction. If the patients are undernourished, the diet must provide liberal amounts of easily digested fats and proteins. In obese persons, however, the intake of carbohydrates and fats must be restricted. Meals should be frequent but not large.

*Sex Ratio in Congenital Clubfoot. C. Mau.—p. 94.

Sex Ratio in Congenital Clubfoot.—Mau presents a collection of domestic and foreign statistics on clubfoot which includes 27,843 cases and shows that 66.59 per cent of the patients are male and 33.41 per cent are female. This 2:1 sex ratio of congenital clubfoot remains constant (in space as well as time). Research on twins shows that the probability of manifestation is comparatively slight but that it affects twice as many males as it does females. It is to be assumed that the abnormal sex ratio is not produced by the anlage that is at the basis of the defect but is connected with peculiarities of gene manifestation. The immutability of the sex ratio of congenital clubfoot suggests sex-linked modifiers which influence the manifestation of clubfoot constantly in the ratio of 2:1 without being themselves subject to manifestation fluctuations.

Bulletin of the Naval Medical Association, Tokyo

- *Observations on the Management of War Injuries to the Genitourinary Organs. Y. Nakauchi.—p. 397.

War Injuries of Genitourinary Organs.—Nakauchi analyzed 51 cases of war injuries of the genitourinary organs sustained by the navy crew during the early part of the Chinese war. Of the total patients treated, injuries of the lower urinary tract and the external genitalia were found in 24 (47.1 per cent); of the upper urinary tract, including the kidneys, in 18 (35.3 per cent), and of the urinary bladder in 9 (17.8 per cent). No patient with injuries to the ureters was encountered. The mortality depends on the extent of complications, particularly those of the gastrointestinal tract; in the presence of complications the primary treatment should be directed to them. Unless the renal injury is associated with extensive destruction with hemorrhage, treatment should be conservative. Involvement of the ureter is relatively infrequent but difficult to diagnose; treatment of this condition consists in the establishment of an adequate urinary flow. Injury to the bladder is by far the most important condition which demands a rational management, and the necessity of free urinary excretion and defecation cannot be overemphasized as an essential phase of effective

treatment. The most common type of damage encountered was injury to the lower part of the urethra and the external genitalia; the important point in the treatment of such injury is to avoid the possibility of deformity following complete cure of the initial injury.

*Influence of High Pressure on Erythrocyte Count and Hemoglobin. K. Okuda and N. Sato.—p. 1299.

*Observations on Machine-Oil Acne. S. Suga.—p. 1305.

Erythrocytes Under High Pressure.—Okuda and Sato studied the effect of high pressure on the erythrocyte count and hemoglobin content of 5 healthy men and 4 women divers. The pressure within the tank in which the observations were made was gradually raised to 2 atmospheres, the process of raising or lowering the pressure requiring about thirty minutes. The subjects remained in this tank under high pressure for thirty to sixty minutes; blood examinations, for control determinations, were made just before they entered the tank and again just before the pressure was lowered. In both groups of blood determinations the red cell count showed an average decrease (7.6 per cent in the men and 9.8 per cent in the women), and the hemoglobin values also decreased (3.4 per cent in the men and 5.2 per cent in the women). Thus it is apparent that no significant difference exists in the reduction of either the erythrocyte count or the hemoglobin content under the conditions of these experiments.

Machine Oil Acne.—Suga reports his observations on 12 patients with occupational acne, all of whom were industrial workers who were in constant contact with machine oil. With the exception of 3 women 28, 24 and 19 years of age the condition occurred in young men under 20. The interval of time in which the disease appeared varied from two months to two years, but in the majority of the patients the condition began to manifest itself within four months. Histologically the most conspicuous pathologic change was the keratinization of the epidermis, associated with plugging and swelling of hair follicles due to the development of hornified substances and extensive cellular infiltration around the follicles. Two varieties of occupational acne must be distinguished: (1) the most common form, characterized by the formation of hornified plugs, the amputation of lanugo hairs, lesions inseparable from acne vulgaris, keratinizing acne and pigmentation and crater-like depressions of the skin and seen on the most exposed parts of the body, and (2) the allergic form, typified by lesions on the sites usual in acne vulgaris (the face, back and chest), where the acne lesions are complicated by pustules, large comedos, atheroma and granular scars. This latter form represents the sensitization of the skin to machine oil.

*Tropical Hay Fever. F. H. Ter Heege.—p. 1231.

Tropical Hay Fever.—Ter Heege discusses the various types of pollen and shows that wind-borne pollens are chiefly responsible for hay fever. This report deals chiefly with tropical hay fever in the Netherlands East Indies, particularly Java. The symptoms of tropical hay fever are much like those of hay fever in the temperate zone. The author describes 8 cases of tropical hay fever in which cutaneous tests were made with pollen or pollen extracts of *Zea mays* (corn), *Sorghum andropogon*, coffee and tobacco. Two patients showed a seasonal rhinitis recurring every year, especially during the dry period. For these patients only tests with pollen were made. In the other patients, the hay fever showed an irregular course, and for this reason they were given cutaneous tests not only with pollen but with inhalation and food allergens. These patients showed a multiple allergy. Hay fever in the tropics is often nonseasonal not only because of the irregularity of the pollination periods but on account of multiple allergy. The skin tests for allergens other than pollen are more important in tropical than in nontropical hay fever. With regard to the injection treatment of tropical hay fever, the author says that seasonal as well as nonseasonal treatment can be used, depending on the individual case history.

Hemolysis after Blood Transfusion with Compatible Blood. A. B. Hansen.—p. 2745.

Hereditary Hemorrhagic Telangiectasis.—Raaschou reports on a woman aged 46 who began at 15 to have nosebleeds, which after 35 became aggravated in frequency and intensity. It is affected by effort, trauma, seasonal changes, the menses and the state of mind. During the last five years, the author says, multiple telangiectases have appeared on the tongue, lips and hands. Severe secondary anemia has occurred several times. During a more severe anemia, in 1936 thrombopenia was established. The blood picture at present is normal, apart from a slightly lowered hemoglobin percentage; the bleeding time, according to Duke's method, is six minutes. Histologic examination of a hemangioma from the hand, of the size of a millet seed, showed a regular, strongly keratinizing covering plate epithelium of several layers and with normal structure; in the stratum papillare a number of empty lumens with endothelial lining were seen. At least eight of seventeen members of the family in the last four generations have had hemorrhagic telangiectasis. It appears in both sexes, with simple dominant inheritance. It is incurable, but the prognosis with regard to life is good.

*Diagnostic Significance of Basophil Leukocytes. H. Holmgren and G. Wohlfart.—p. 2771.

Tetany in Sprue Treated with Vitamin D in Intramuscular Injections. H. Hult.—p. 2774.

"Allergic" and "Allergizing" Rheumatic Diseases.—Kahlmeter designates acute rheumatism and chronic polyarthritis as probably "allergizing," not "allergic," disorders and on the basis of 115 cases describes three forms of "allergic" rheumatism: 1. Allergic polyarthritis or polytenositis (75 instances, 55 in women) is, he says, characterized by transient edema, with sometimes intra-articular, sometimes intratendovaginal and sometimes periarticular localization, occurring at varying intervals and as a rule with short duration in each localization. The seat of the edema changes capriciously during the course of an attack. Between the attacks the patient is free from symptoms. Often other allergic symptoms are present, such as urticaria, Quincke's edema, asthma and migraine. 2. In intermittent or paroxysmal neuralgias with vasomotor symptoms (17 instances, 14 in women) there are attacks of sharp pain, localized in the cervical and in the brachial plexus, lasting from some hours to two days at the most, accompanied by paresthesias, vasoconstriction or diffuse edema and returning after variable intervals during which the patient feels perfectly well. These neuralgias are remarkably like attacks of migraine in duration and spacing and also in the effect of variations in meteorologic conditions, the psychic state and so on. As in group 1, other allergic symptoms may be present, such as migraine (in about half of the cases), urticaria and asthma. 3. Hydrops intermittens (23 instances in 10,000 cases of arthritis, 10 in women) is in its typical form a rare disorder. The attacks occur at regular intervals with regular duration and affect the same articulations. In all but 1 of the author's cases one or both knee joints were affected; in 3 cases the right and the left knee were affected alternately for a long time.

Diagnostic Significance of Basophil Leukocytes.—Holmgren and Wohlfart studied the number of basophil leukocytes in patients with different disorders by means of a specific staining method. They state that the number of mast cells seems to have diagnostic and sometimes perhaps prognostic significance. In chronic myeloid leukemia the mast cell count is almost regularly increased. In 5 cases 10 per cent or more was established. A mast cell value of from 4 to 5 per cent is almost pathognomonic for myeloid leukemia. In polycythemia there is a tendency to a slight increase in the number of mast cells, and during recent years transitions from polycythemia vera to myeloid leukemia have been noted.

Book Notices

Insect Pests. By Wm. Chumley Harvey, M.D., D.P.H., M.R.San.I., Medical Officer of Health, Borough of Southgate, and Harry Hill, M.R.San.I., A.M.I.S.E., M.S.I.A., Sanitary Inspector, Borough of Southgate. Cloth. Price, \$4.25. Pp. 292, with 23 illustrations. Brooklyn: Chemical Publishing Company, Inc., 1941.

The control of insect pests is a problem which merits serious consideration at any time, but the present troubled international situation with its resulting altered living conditions and its movement of fighting and civilian forces has precipitated even closer attention to the problem. This volume is especially useful in that it presents the necessary practical considerations in hand-book form. Although the manuscript was written in England, the subject matter is discussed in terms which are applicable to any country. Unnecessary detail is omitted, the authors having confined their remarks to the essentials required by the average department for insect control. Of the fourteen chapters in the volume, five relate to specific insect pests: general outlines of insect control, the bedbug, the flea, the louse and other insect pests. The last mentioned chapter discusses the cockroach, its relation to disease, habits, dissemination and control, the cricket, the silver-fish, the ant, the itch mite, psocids, the earwig, woodlice and the house fly. The remaining chapters deal with the principles and practice of disinfestation: building construction and infestation, gaseous fumigants, the technic of fumigation, insect control and educational measures, legislative control, human toxicology, disinfestation of foodstuffs and disinfestation of ships. The chapter on human toxicology discusses only hydrogen cyanide. The volume also has two appendices, one presenting forms and records, the other specimen propaganda leaflets. The index is adequate for the contents of the book. Written in a style which permits easy and fast reading, the present volume should have a useful place as adjunct reading for all who are interested in the control of insect pests and in the prevention of disease. As the book is concerned only with insect pests commonly encountered around human dwellings, the reader must not expect to find discourses on special problems such as mosquito control.

Developmental Diagnosis: Normal and Abnormal Child Development. Clinical Methods and Practical Applications. By Arnold Gesell, M.D., and Catherine S. Amatruda, M.D. Cloth. Price, \$6.50. Pp. 447, with illustrations. New York & London: Paul B. Hoeber, Inc., 1941.

This book aims to make the researches in normal mental growth during the first five years carried on over a period of twenty years at Yale University available and clinically useful to the pediatrician and the family physician. Numerous publications by Dr. Gesell and his co-workers have already recorded his extensive investigations into normal development of the young child, but this book summarizes and correlates the material for the clinician. The first part of the book offers a general survey of the early development of the child, including the norms of development up to the age of 3 years. The nature and conduct of the developmental examination of the young child are discussed. This first part of the book gives the substance of the authors' studies of the normal infant.

The second part of the book deals with defects and deviations of development. This is a most valuable section, which will be appreciated by physicians who tend to be baffled by problems of mental retardation. Differential diagnosis, in terms of the authors' use of the developmental quotient, is succinctly dealt with, and an etiologic classification of developmental defects and deviations is offered. Mental retardation, endocrine and convulsive disorders are discussed diagnostically. A chapter on special sensory handicaps is particularly informative. A discussion of clinical aspects of child adoption presents an excellent point of view with which all physicians should be familiar.

The final section, on protection of early child development, considers the use which the authors' diagnostic studies may be put to in furthering the proper early supervision of children and in guidance toward healthy physical and mental development. It is recommended that all medical students and youthful physicians read the small section entitled "Imparting a Diagnosis" (p. 312). Here some important mental health considerations in dealing with retarded children are stressed. Several appendixes

give much detail of examination technic, charts showing growth trends, equipment required for developmental diagnosis and information on cinematic case studies.

This book may be warmly recommended to pediatricians and physicians. It offers comprehensive and well organized information about infants and children. The authors state specifically that they are chiefly concerned with the maturity and organization of the neuromotor system; with developmental neurology. This approach, most useful as it is, results in less emphasis on some psychologically and psychiatrically important aspects of child development. The intense focusing of interest on the conduct of the infant is not paralleled or supplemented by equally full consideration of his primary relationships with the mother and other members of the family. These considerations are not neglected in the book but are not sufficiently brought into focus to give as fully rounded a picture of the early development of the child as the rich material of the book might permit.

A word of caution also is in order. It would be easy to gain the impression that the use of the developmental schedules and the conduct of the developmental examination is a simple matter and that any physician without particular preparation might apply them in his office practice. As a matter of fact, if authentic use of Dr. Gesell's developmental norms is to be made, the physician should be carefully schooled and practiced in the conduct of the examination, and the greatest care and meticulousness exercised. Successful use of the examination, particularly for prognostic purposes, requires closest attention to very minor deviations in the infant's responses. The use of the refined tool Dr. Gesell has developed calls for skill and precision, and therefore training in its use. The volume is well printed, the language throughout is clear, simple and concise, and there are abundant photo tracings.

The United States of America, Appellants, vs. The American Medical Association, A Corporation; The Medical Society of the District of Columbia, A Corporation; The Harris County Medical Society, An Association, et al., Appellees. (A Reprint of the Official Documents with a Condensation of the Trial.) Cloth. Price, \$5. Pp. 532, with illustrations. Chicago: American Medical Association, 1911.

This volume, bound in a durable green cover, contains a complete chronological review of the several steps in the criminal action instituted by the United States against the American Medical Association, the Medical Society of the District of Columbia, the Washington Academy of Surgery, the Harris County, Texas, Medical Society and twenty-one individual defendants, an action in which the defendants were charged with conspiring to violate the Sherman Antitrust Act in that they allegedly conspired unlawfully to interfere with Group Health Association, Inc., of the District of Columbia. The material contained in the book, all of which was previously published in *THE JOURNAL*, is presented in three groupings. In the first grouping, dealing with events occurring before the trial, will be found a verbatim copy of the statement released by Thurman Arnold, Assistant United States Attorney General, on Sunday, July 31, 1938, in which a grand jury investigation of the medical profession was forecast. This statement prompted widespread newspaper editorial comment, and following the Arnold statement in the book are reproduced many of such leading editorials. On October 17, 1938 a grand jury in the District of Columbia was impaneled, and an indictment was returned against all of the defendants on December 20 of that year. A copy of this indictment is reproduced on page xxiii. Beginning on page xxix is a chronological record of the events leading up to the indictment, followed by the opinion of Justice Proctor declaring the indictment invalid, the opinion of the United States Court of Appeals for the District of Columbia overruling Justice Proctor and reference to the ruling of the United States Supreme Court, in which a petition for a writ of certiorari filed by the defendants to review the action of the Court of Appeals was denied. Interspersed among the official documents are many pages of editorials from *THE JOURNAL*, newspaper editorials and cartoons, and photographs of the individual defendants and the attorneys for the government and for the defendants. On Wednesday, Feb. 5, 1941 the case came to trial on its merits and the second part of this book consists of a transcript of the record in the case, including the opening statements of counsel, the testimony of witnesses both for the government and for the defendants, copies of all motions made

and of the court rulings thereon, the closing arguments of counsel and the instructions given by the court to the jury. The third grouping comprises references to the verdict of the jury, in which the American Medical Association and the Medical Society of the District of Columbia were found guilty and the other defendants not guilty. The book ends with a report of the Board of Trustees to the House of Delegates, in which the Board recommended that counsel for the Association be directed to appeal the judgment that was rendered against the Association. The House of Delegates, without a dissenting vote, approved the report. Within the covers of this book, therefore, will be found a complete picture of the controversy extending over a period of more than three years. In no other place can the important happenings in this important case be found in so accessible a form. Many critical questions relating to the future of medicine in the United States are dependent for answers on the final judgment yet to be rendered in this case, questions that may affect the private practice of each and every physician and of each and every other professional man. Scattered through this book will be found set forth these questions with the answers suggested by the government and the answers suggested on behalf of the medical profession. The Supreme Court of the United States will undoubtedly be afforded an opportunity to say which answers are correct. The importance of the issues involved have prompted the publication of the book, and it should be in every physician's library. It should be available in every public library and in the library of every attorney or other professional man who is concerned with what the future may hold in store for the professions.

The Intervertebral Disc with Special Reference to Rupture of the Annulus Fibrosus with Herniation of the Nucleus Pulposus. By F. Keith Bradford, M.D., and R. Glen Spurling, M.D. Cloth. Price, \$4. Pp. 158, with 45 illustrations. Springfield, Illinois & Baltimore: Charles C. Thomas, 1941.

The amount of literature on the intervertebral disk and the nucleus pulposus has increased so tremendously during the past decade, and the diagnostic procedures and methods of therapy have varied so significantly, that the broad point of view of the authors in this monograph is extremely welcome. The embryology, anatomy, physiology and pathology are thoroughly described. The symptomatology, diagnosis and differential diagnosis and diagnostic methods are discussed in detail. In reviewing the literature the authors emphasize those conditions which are described and presented with a proved pathologic basis, while certain reports are mentioned but not accepted at face value. Phenomena which have been observed repeatedly have been given acceptance without known satisfactory explanation.

The authors stress the fact that the diagnosis of rupture of the annulus fibrosus with posterolateral herniation of the nucleus pulposus must not be undertaken lightly and that familiarity with other pathologic conditions with similar appearance is necessary. The description of the methodical clinical, roentgenologic and laboratory examination of patients with low back and sciatic pain bears favorable comment. The roentgenograms help to exclude lesions other than those due to pathologic conditions of the disk. The use of iodized oil is indicated only when the diagnosis cannot be made without it.

While it is true the presumptive clinical diagnosis of herniated nucleus pulposus can be made on the basis of back pain, with persistent or remitting sciatic pain and a positive sciatic nerve stretching test and hypesthesia and well localized paresthesia, or causalgia in the lateral aspect of the leg or in the foot, the differential diagnosis must be made from primary or metastatic neoplasm of the spine, cauda equina tumor, neoplasm of the prostate, rectum or pelvic viscera, spinal injury or anomaly, narrowing of the intervertebral foramina from other causes, hypertrophy of the ligamentum flavum, spondylolisthesis, syphilis, sciatic nerve injury, abscess secondary to bone suppuration, neurofibroma, peripheral tumor, herpes zoster, sciatic pain following gluteal injections, hypertrophic arthritis, aneurysm of the iliac or popliteal artery, glomus tumor, vascular disease and polyneuritis.

The authors emphasize the fact that low back disability from intervertebral disease without root pain is almost always an orthopedic problem. Conservative measures should be used in

all acute cases. Laminectomy is indicated without contrast myelography if the symptoms persist and the subjective and objective appearances are characteristic. The technic of laminectomy at the various levels is described in detail. The post-operative care and end results are discussed. There is a short chapter on cervical and thoracic herniations and another chapter which includes some selected case reports.

This timely book is conservatively written and well illustrated. It has a fairly complete bibliography. It should be welcomed by all those who see or treat back pain and "sciatica," be they general practitioners, neurologists, neurosurgeons or orthopedic surgeons.

Arthritis in Modern Practice: The Diagnosis and Management of Rheumatic and Allied Conditions. By Otto Steinbrocker, B.S., M.D., Assistant Attending Physician and Chief, Arthritis Clinic, Bellevue Hospital, Fourth Medical Division, New York City. With Chapters on Painful Feet, Posture and Exercises, Splints and Supports, Manipulative Treatment and Operations and Surgical Procedures. By John G. Kuhns, A.B., M.D., F.A.C.S., Chief of the Orthopedic and Surgical Service, Robert Breck Brigham Hospital, Boston. Cloth. Price, \$8. Pp. 606, with 321 illustrations. Philadelphia & London: W. B. Saunders Company, 1941.

This most recent of the monographs on arthritis is designed to embody in concise and practical form the commonly accepted diagnostic and therapeutic measures which are proving useful for arthritis but which are too new to have found a place in the textbooks. A good deal of judgment in employing any of them, as the author himself points out, is necessary, and, in the main, Dr. Steinbrocker has chosen well. Nevertheless, some procedures of a highly questionable nature have crept in, such as the recommendation for high colonic irrigation every two to four weeks. The chapter on local and regional analgesic injections is especially interesting. It is probable that the author goes further in his belief in the usefulness of such measures than do most workers in the field, but it is certainly a subject which deserves careful investigation. Analgesic injections are not without risk, however, and should be indulged in only by those who are thoroughly qualified by special study and training. The last five chapters of the book are written by Dr. J. G. Kuhns and deal with painful feet, posture and exercises, splints and supports, manipulative treatment, and operations and surgical procedures. These contain much practical information. The chapter on posture and exercises opens with a discussion on methods of grading posture and includes a reproduction of the Harvard chart of body mechanics, which grades posture on the basis of the silhouette. Although the chart is widely used, this method of grading is based largely on the degree of lordosis, and the entire question of lordosis in its relations to posture and "body mechanics" probably deserves complete reevaluation. In the way of minor criticisms, the references given at the end of each chapter are not readily legible because of the indentions; there are also some names misspelled in the bibliography. In spite of minor criticisms, this is a useful book and should serve as considerable assistance to physicians in the management of patients with the various common forms of arthritis.

America's Housekeeping Book. Compiled by New York Herald Tribune Home Institute. Cloth. Price, \$2.50. Pp. 607, with illustrations. New York: Charles Scribner's Sons, 1941.

The vast amount of material collected by the New York Herald Tribune Home Institute is here made available in book form. Every housewife can find here innumerable useful hints on laundering, housecleaning, money management, repairing, operation and maintenance of the home, painting and, in fact, everything except cooking. The book, therefore, forms an essential companion book to the cook book in every kitchen.

Nobel Prize Winners: Charts—Indexes—Sketches. Compiled by Flora Kaplan. Second edition. Cloth. Price, \$2.50. Pp. 144, with portrait. Chicago: Nobelle Publishing Company, 1941.

This is the second revised edition of a previous publication by the same author. Her first edition was sent to the Nobel Prize Foundation at Stockholm, Sweden, which made the necessary corrections and revisions. The present edition bears the marks of this improvement. The book is a most complete collection of biographic sketches and other information anywhere available to the recipients of the Nobel prize.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

FRACTURES, TRAUMA AND GLYCOSURIA

To the Editor:—Shortly after a patient has suffered a fracture, he may show a slight glycosuria. Can you offer any explanation for this condition, and can you state whether or not my observation is consistent with that of others? N. H. Farrell, M.D., American Falls, Idaho.

ANSWER.—Glycosuria frequently is found after a fracture. This observation rarely has any serious or medicolegal importance. What must be excluded, of course, is the presence of diabetes.

It has never been proved that ordinary trauma can cause diabetes mellitus. It is conceivable that the pancreas itself could be traumatized to such a degree as to produce diabetes, but actual instances are extremely rare. On the contrary, there are many instances in which severe trauma to the pancreas, with or without acute pancreatitis, has not produced diabetes mellitus.

There are several points worth mentioning: 1. Trauma often produces glycosuria, but this does not necessarily mean diabetes mellitus. It does mean that the diagnosis of diabetes mellitus must be excluded. 2. Trauma, either physical or psychic, may cause latent diabetes to be readily apparent. There are numerous instances in which a mild or latent diabetes is made severe by a fracture, an automobile accident or a sudden death in the family. 3. Trauma may increase the severity of diabetes. Herbert Pollack (The Influence of Bone Fracture on Insulin Requirements in Diabetes Mellitus, *Proc. Staff Meet., Mayo Clin.* 8:423 [July 12] 1933) reported observations on 3 diabetic patients who sustained fractures. One of these patients may have had an undiagnosed fracture of the base of the skull. It should be mentioned that a fracture in this region may produce the diabetes described by Claude Bernard. 4. If trauma were responsible for the development of diabetes, then the extreme trauma produced by modern warfare should have caused an increase in the incidence of the disease among the combatants of the war of 1914 to 1918. Both E. P. Joslin (The Treatment of Diabetes Mellitus, ed. 6, Philadelphia, Lea & Febiger, 1937) and R. M. Wilder (Clinical Diabetes Mellitus and Hyperinsulinism, Philadelphia, W. B. Saunders Company, 1940) recorded that this was not the case; more cases of diabetes were found among noncombatants than among combatants.

SOLUTIONS OF SODIUM SULFATHIAZOLE IN NOSE

To the Editor:—Recently there was an article in *The Journal*, April 26, 1941, page 1899, on the successful treatment of sinusitis with nasal sprays of 5 per cent solution of sodium sulfathiazole. Before and since, there have been published positive statements that it should be used only intravenously, as any spilled outside the vein causes necrosis. In a personal conversation which I held with the head chemist of a large drug manufacturing company, the chemist stated positively that a solution of sulfathiazole exposed to light begins to decompose after forty-eight hours and becomes irritating as well as loses its chemotherapeutic effect. He stated that it is not safe to use intranasally as a spray after several days. If it is destructive to tissue, must it not destroy the delicate intranasal cilia when sprayed in? If the drug is so used continuously for some time, the most powerful protective function against infection of the nose would ultimately be destroyed, as in cases of ozena or advanced chronic atrophy. Has any research work been done to determine the effect of sulfathiazole on viable cilia?

A. C. Howe, M.D., Brooklyn.

ANSWER.—A 5 per cent solution in distilled water of sulfathiazole sodium sesquihydrate has a pH of between 10 and 11, and when such a solution is injected into the tissues it has a definitely irritating effect and under certain conditions will produce necrosis of the tissues with slough. However, when such a solution is used as a spray in the nose or the throat there is a rapid dilution of the original solution, together with a decrease in its alkalinity due to the buffering action of the nasal mucus and saliva, so that the chance of irritating effects being produced is decreased. When a 5 per cent solution is used as a spray at frequent intervals, patients may complain of a sensation of heat and burning in the area to which the spray of the solution of sodium sulfathiazole has been applied. Fletcher (*California & West. Med.* 55:94 [Aug.] 1941) has reported that necrosis of the lining of the maxillary sinus occurred after

irrigations of the sinus with solutions of sodium sulfathiazole for three weeks. Solutions of the sodium salt of sulfathiazole may decompose if exposed to light over several days. For this reason when sprays of sodium sulfathiazole solution are being employed the prescription should be written for a two days' supply in order that a decomposed solution is not used by the patient. As far as is known at present, there have been no studies conducted on the effect of sprays of sodium sulfathiazole on the cilia of the nasal passages. Certainly it would seem that injury might come to the cilia if highly alkaline solutions were employed, but it is possible (and this is solely a matter of opinion) that the dilution and buffering effects of the nasal mucus are such that the cilia are not affected. A final conclusion on this point cannot be reached at present because of the lack of experimental work. Until the results of such investigations are available, it would seem that a considerable degree of caution should be used in the application of alkaline solutions of sodium sulfathiazole to the nasal mucous membrane.

ARM AND LEG PAINS IN BOY

To the Editor:—About ten months ago a boy aged 8 years had nasal obstruction, frequent sneezing and vague aches and pains about the arms and legs. On examination, he was found to be 3 pounds (1.3 Kg.) underweight and exceptionally sensitive to ragweed pollen and to have mild secondary anemia. The heart and lungs were normal and the liver and spleen not enlarged. He was given specific therapy to combat the hay fever and anemia; at present he has gained 10 pounds (4.5 Kg.) and is free from the nasal allergy. However, the pains in the upper and lower extremities have become more intense, and sedation is required to make him comfortable. These pains come on when it is about to rain or snow. The boy is not affected by swimming in cold water or exposure to dry cold, but atmospheric changes seem to predispose to these attacks of pain. At no time have the joints or extremities been swollen, tender or limited in motion. The sedimentation rate is normal. The blood calcium content is 11 mg. per hundred cubic centimeters, the phosphorus 4.6 and the nonprotein nitrogen 37 mg. The blood pressure is 98 systolic and 68 diastolic. A roentgenogram of the long bones shows mild, diffuse osteoporosis. Repeated examinations of the urine have given negative results. The mother is fearful that the child has "rheumatism" which may eventually lead to crippling heart disease. What conditions would give pain in the extremities associated with atmospheric changes? What form of relief would you suggest? M.D., New York.

ANSWER.—This boy has a peculiar clinical picture and has already been well studied from a physical and laboratory standpoint. The following conditions come to mind, most of which have already been fairly well eliminated by the data presented: hyperparathyroidism, chronic polyarthritis (Still's disease), myalgia, growing pains, rheumatic fever, neuritis, neuritis (lead poisoning, beriberi), scurvy, muscular dystrophy, sickle cell anemia (if the patient is a Negro), myositis, trichinosis, and physical allergy.

The four most likely differentials would involve rheumatic fever, growing pains, physical allergy and neuritis.

Growing pains occur at the end of the day, especially during the night, and the pain is gone in the morning and usually does not recur during the day. They appear most commonly in the muscles of the legs and thighs, appear rarely in the upper extremities and are frequently worse in the summer, when children are more active. There are no objective signs or other evidence of rheumatic fever. The sedimentation rate, leukocyte count and hemoglobin content should be normal.

In patients with rheumatic fever the pain and stiffness occur when getting out of bed in the morning and during the entire day, especially on motion, often causing a limp. The patient feels better on getting warm in bed. The joints rather than the muscles are particularly involved in both the upper and the lower extremities. There are usually bouts of joint pains, nose-bleeds, cutaneous rashes, pallor and fever. There is almost always during the acute painful stage an increased sedimentation rate, some fever, some anemia and a mild increase in leukocytes.

Physical allergy must be considered, as the child mentioned is allergic. This particular group of symptoms has not been described, but it is conceivable that damp weather—increased humidity and low barometric pressure—could cause some sort of physical allergy resulting in muscular spasm and pain. It would be difficult to prove this. However, if epinephrine or ephedrine in proper doses relieved the symptoms the relief would be suggestive.

In a child of 8 years a neurosis must always be considered, the complaints being an attempt to attract attention or gain some end. However, other behavior difficulties would be present in a child poorly adjusted emotionally, and no mention is made of maladjustment in the history.

The osteoporosis of the long bones should be followed by occasional roentgenograms, as the child might have an incipient parathyroid disturbance.

BACTERIA AND SPIROCHETES IN THE STOMACH

To the Editor.—A white man aged 33 complains of morning nausea and gaseous eructation and anorexia. On examination of the gastric content 40 degrees of free acid was found and 50 degrees of total acid. This was thirty minutes after 7 per cent alcohol. It was noted that the gastric content had a foul odor and simulated that of fusospirochetal abscess. On examination of the gastric sediment numerous pus cells, particularly mononuclear cells, and a great many fusiform bacilli and spirochetes were found. I was unable to find any spirochetes in smears from the mouth or throat. Roentgen examination of the chest and stomach revealed no abnormalities. The patient was given 0.3 Gm. of neosarsphenamine twice weekly for four doses, and following this he has gained considerably in weight and feels better. There was a severe reaction after each injection. Now he is taking nothing, but the gastric content continues to have the same foul odor and the same findings in the sediment. I should like to know the frequency of such a finding and also the therapy.

M D, South Carolina.

ANSWER.—Fusiform bacilli and spirochetes may be found in the mouth and stomach contents of healthy persons. Large numbers of these organisms may also be found in the gastric contents of patients with achlorhydria, particularly in those with pernicious anemia (Dick). The significance of this finding is not known, but ulcerative lesions of the gastric mucosa are not commonly found in pernicious anemia.

Bacteria are swallowed almost constantly, including those from infections in the mouth and the respiratory tract. Examination of the gastric sediment may therefore be expected to disclose a large number and variety of bacteria, not infrequently including pathogenic organisms. Whether or not these bacteria remain viable for more than a few minutes is thought to depend almost entirely on the acidity of the gastric contents. In the presence of free acid (pH value of 3 or less) the stomach contents are bactericidal and when cultured are almost always sterile. In the acid secreting stomach there may normally be periods of hours each day when the gastric contents are not sufficiently acid to be bactericidal. If pathogenic bacteria are swallowed during such a period, it is conceivable that they might invade the gastric mucosa and subsequently give rise to an inflammatory lesion. The frequency of such an occurrence is not known. The available evidence would seem to indicate, however, that for some reason as yet not clearly understood the gastric mucosa is resistant to infection. With regard to the etiology of chronic nonspecific gastritis, Schindler states that practically nothing is known but "it seems that bacteriological factors play a minor role as compared with mechanical and chemical factors."

The cytology of the gastric contents has been studied by several investigators. The average cell count in the normal subjects studied by Mulrooney was found to be 232 per cubic millimeter: 16 per cent were leukocytes and 84 per cent were epithelial cells. In cases of gastritis an increase in the total cell count was found together with a relative increase in the leukocytes. The significance of leukocytes in the gastric contents would therefore seem to depend entirely on the number of leukocytes present.

In view of these considerations, additional information is necessary to evaluate the findings in the case cited and to institute appropriate therapy. Gastroscopy should readily disclose whether or not an ulcerative and suppurative gastric lesion is present. Cultures of the saliva should indicate whether fusiform bacilli and spirochetes are being swallowed and, if so, their relative number.

EFFECT OF DRUGS ON INTESTINAL pH

To the Editor.—Are there any drugs, other than hydrochloric acid, which will tend to acidify the intestinal tract or at least reduce the alkalinity of it? Would sodium acid phosphate or ammonium chloride have the same effect on the gastrointestinal acidity as they do on the urinary acidity?

G. Perry Ross, M.D., Auburn, N. Y.

ANSWER.—The effect of various drugs on the reaction of intestinal contents (except in the duodenum) has not been thoroughly investigated. It is doubtful, however, that ammonium chloride, sodium acid phosphate, other acid salts or acids administered in therapeutically possible doses alter the pH of the intestinal contents long enough to be of practical significance. Certainly the effect is not comparable to that on the pH of urine. Dilution, neutralization and rapid absorption, among other factors, tend to prevent an appreciable concentration of such drugs in the bowel.

When the stomach secretes acid, considerable variation in the pH of intestinal contents may occur, although the reaction below the duodenum is usually alkaline to slightly acid, with a tendency for the contents to be alkaline lower in the bowel.

Whether the intestinal contents are constantly alkaline in the presence of achlorhydria is not definitely known. In view of the fact that a normal person has been estimated to secrete approximately 1,500 cc. of acid gastric juice daily, however, replacement therapy does not seem to be practical. Furthermore, there is no conclusive evidence to indicate that such therapy would be sufficiently beneficial to warrant its use.

BODY SWELLINGS PRECIPITATED BY PRESSURE

To the Editor.—A married woman aged 32 has been complaining of constantly recurring itchy, at times red, welts over various parts of the body. They occurred at first just before menstruation but they occur now any time during the menstrual cycle. Pressure of some sort seems to be the provoking and precipitating cause. Thus a tight belt around the waist, pressure of strap of a golf bag over the shoulder, tight shoes across the dorsum of the foot, leaning a long time on the tips of the elbows or sitting a long time on a hard surface will cause the manifestation of a welt from 1 inch to 3 inches in diameter over the area of the body subjected to the pressure. There is a history of allergy in the family. Otherwise the history by systems, the past medical history and the family and social histories are negative. The blood Wassermann reaction is negative, a catheterized specimen of urine was negative on analysis, blood counts revealed mild secondary anemia. The basal metabolic rate was minus 12 and minus 18 per cent. The treatment consisted of large doses of calcium, thyroid, desensitization with histamine hydrochloride, administration of histaminase, large doses of vitamins, ephedrine and amylo, adrenal cortex extract and ascorbic acid. Is there any other form of treatment which might possibly be tried to help her? The condition has improved somewhat; that is, the welts are not so large, itchy and frequent as formerly, but much room for improvement remains.

M D, Milwaukee

ANSWER.—The diagnosis in this case is not at all clear. The fact that pressure precipitates the swellings leads to the diagnosis of physical allergy due to pressure, the treatment of which is unsatisfactory. Pressure should, of course, be avoided as much as possible. The fact that it occurs at menstruation would suggest some ovarian disorder. Possibly the patient is allergic to certain foods, and menstruation acts merely as a contributory factor. The patient should avoid for a trial period foods which commonly cause urticaria, such as fresh vegetables, fresh fruits, chocolate, tomatoes, peas, beans, fish, "cola" drinks, nuts and pork, including ham, bacon and lard.

THE CHEDIAK SERODIAGNOSTIC TEST FOR SYPHILIS

To the Editor.—A serodiagnostic test for syphilis described by Chediak of Hoboken has recently been brought to my attention. This is a micro-agglutination reaction based on the use of one drop of dried blood, and the result can be read within a few minutes. The method is extremely simple, and the author claims greater accuracy than is to be had with the Wassermann, Kahn, Meinicke and other tests. The advantages of such a simplified test for syphilis are obvious. Although seventy-five references are quoted by Chediak as appearing in the Cuban, Spanish, South American, French, German and Italian literature and regarding the use of his reaction, there is not one American or English article quoted on it. As facilities for investigating the literature at this station are non-existent, I should like information on the accuracy and reliability of this reaction. It appears to me strange indeed that, if this test is accurate, physicians in the United States are really missing a simple and readily available test for syphilis.

Emil Granet, M.D., Lieut., M. C., U. S. N. R., Guantanamo Bay, Cuba

ANSWER.—It is apparently true that the Chediak microtest for syphilis has not been discussed in the medical literature of this country. The *Quarterly Cumulative Index Medicus* from 1936 on does not list any English references to the test, although it does list references in other languages. The reason is probably that serologists in this country prefer the use of serologic tests which have been evaluated by the American Evaluation Committee on Serodiagnostic Tests. It is understood that the Chediak reaction will be evaluated with other serologic methods in a forthcoming study to be conducted by the U. S. Public Health Service.

To secure the Chediak reaction, which is a modification of the Meinicke microreaction, a drop of defibrinated blood is permitted to dry on a slide. The dried drop is dissolved by a mixture of sodium chloride and sodium bicarbonate solution. An antigen similar to that of Meinicke is added: the slide is agitated for three minutes and is then placed in a moist chamber for thirty minutes. The results are read microscopically. A full description of the Chediak reaction with a review of the literature is contained in a recent volume: *Vogelsang, T. M.: Sero-Diagnostic de la Syphilis*, Bergen, Norway, J. W. Eides Boktrykkeri, 1940.

CONGESTIVE HEART FAILURE

FACTORS INFLUENCING THE ULTIMATE PROGNOSIS

THOMAS J. DRY, M.B.
ROCHESTER, MINN.

The immediate results of the treatment of congestive heart failure due to any cause often are very gratifying. This is especially true of the first break in cardiac compensation. Indeed, the ease with which an edematous patient may be rendered fluid free and the ease with which he is relieved of distressing symptoms by the appropriate use of effective diuretics may lead the patient readily into the mistaken belief that his disease has been cured and that presently he will be able to return to his former mode of living. As the mechanism responsible for congestive heart failure is in most cases an irreversible process with a strong potentiality to progression, it can be assumed safely that cardiac decompensation will recur sooner or later—certainly sooner rather than later if the patient is allowed to foster his conviction of having been restored to normal health by the treatment which has been dispensed to him.

It was with the idea of ascertaining, if possible, what factors, if any, might influence the course of patients whose hearts had been decompensated that this study was undertaken.

Data were procured through the clinical records or through follow-up letters on 150 patients who had received hospital care in the cardiac service for congestive heart failure. These cases, although they were not strictly consecutive, are not selected in any way and should represent a fair cross section of the cases from year to year. The measures employed for the restoration of cardiac function in these cases were essentially those which are recognized universally as the standard method of treatment. These consisted of the use of digitalis and diuretics (mercurial, "acid producing salts," so called, and the xanthine preparations) either individually or in combination, depending on the indications in the individual case, of restriction of fluid and salt and of outlining a protective regimen after the patient had become ambulatory. All patients were strongly urged to establish contact with their family physicians at an early date after their dismissal, so that recurrences of failure might be promptly treated.

ETIOLOGIC FACTORS

In 114 patients (76 per cent) cardiac decompensation was on the basis of hypertension and coronary disease either independently or in association with each other:

in 24 patients (16 per cent) the diagnosis was rheumatic heart disease (in 1 of these the diagnosis was Pick's disease); hyperthyroidism was present in 7 patients (4.7 per cent), in 3 in association with hypertension, and in 2 with coronary disease, and 1 patient had rheumatic mitral stenosis. In 3 patients syphilitic aortitis was regarded as the cause of the cardiac failure and in 2 patients the main underlying cause of decompensation was thought to be obesity, although both patients were within the arteriosclerotic age and coronary disease may have played an important part in the breakdown of their cardiac reserve.

Age Distribution.—The majority of patients were between the ages of 50 and 69 years, inclusive (table 1). The average age of the entire series of patients was 57.5 years.

Sex Distribution.—There were 106 men and 44 women, a ratio of about 5:2.

SUBSEQUENT COURSE

At the time when the survey was completed, 128 of the 150 patients had died and only 22 were living. With the aid of the Division of Biometry and Medical Statistics of the Mayo Clinic a survival curve was plotted (reproduced in the accompanying chart). The methods of calculating the necessary data followed the regular principles used in actuarial practice, since some of the patients were still alive at the conclusion of the study. This curve gives the expected number of persons out of 100 who will be living for consecutive years after the first episode of congestive failure. The chart indicates also, for comparison, the computed life expectancy curve for the normal population as well as that for patients who have had another serious disease, namely carcinoma of the stomach in which gastric resection had been carried out (that is, patients with carcinoma of the stomach who were considered to have had operable lesions). The descent of the curve not only is steep, indicating a heavy mortality from year to year, but also continues on practically a straight line, so that only 13 patients out of the original 100 can be expected to be alive at the end of nine years.

In order to determine what factors might have influenced the prognosis in the individual case of congestive heart failure, the records of this group of patients were analyzed, first, by comparing the data relative to those who lived five years or more after the first episode of heart failure with the data relative to those who died within five years after the onset of congestive heart failure; and, second, by a detailed study of the records of those patients who were still alive at the completion of the survey. In this group it was possible to ascertain data not always available among those who had died.

COMPARISON OF DATA RELATIVE TO PATIENTS WHO
LIVED FIVE YEARS OR MORE WITH DATA ON
THOSE WHO DIED WITHIN FIVE YEARS

Of the entire group, 40 patients survived for five years or longer, and 110 died within five years after their first break in cardiac compensation. The signifi-

cant data relative to the two groups are summarized in table 2. Among those who lived five years or more there were a greater proportion of persons in the earlier decades of life (45 years or less), a greater proportion of women and a greater proportion of patients who had rheumatic heart disease than among those who lived less than five years.

The group that had rheumatic heart disease is not large enough to establish differences in prognostic trends as determined by the different valvular lesions, but other studies¹ have illustrated the difference in the life history of patients who have mitral endocarditis on the one hand and those who have aortic valvular disease of rheumatic origin on the other. In short, it may be stated that aortic lesions are tolerated better than is mitral stenosis, so that there is a tendency for

congestive heart failure to supervene earlier in patients who have mitral disease than in those who have rheumatic aortic lesions. At the same time compensation, once restored, is maintained poorly by patients who have rheumatic aortic lesions,² in contrast with those afflicted

with mitral stenosis, who may respond quite satisfactorily to treatment through repeated episodes of recurrent congestive heart failure. The poor outlook of patients who have syphilitic aortitis associated with congestive heart failure has been recognized universally.

The incidence of cardiac hypertrophy was not found to be significantly at variance in the two groups of cases. It must be recalled here that this study deals with patients whose cardiac reserve had been exhausted to the point of outspoken congestive heart failure. In a comprehensive study carried out by Grant,³ comprising 1,000 men in whom organic heart disease had been discovered ten years prior to his survey, among recruits of the last World War, it was shown clearly that the larger the heart the more likely was congestive heart failure to ensue. These patients were the ones who were noted also to have a corresponding degree of limitation of tolerance to exercise—the most reliable criterion whereon to base a cardiac prognosis.

It would seem that, after congestive heart failure has entered the picture, new factors assume importance in determining the future progress of the patient.

Fig 1.—Survival curves for patients who have had congestive heart failure, for the normal population and for patients on whom gastric resection has been performed for carcinoma of the stomach. The last named survival curve is based on studies carried out by Walters and his associates.

A comparison of the electrocardiographic findings in the two groups is of interest and at first sight the differences would seem significant from the standpoint of prognosis. Thus there is a higher incidence of electrocardiographic abnormalities among the group of patients who succumbed during the first five years after the initial break of cardiac compensation. There is also a higher incidence of conduction defects (auriculoventricular as well as ventricular conduction disturbances) and of significant T wave alterations (comprising changes in the T waves either in lead 1 only or in leads 1 and 2, in the T waves of leads 2 and 3 or in the T waves in all three conventional leads). In this connection it should be recalled that the almost universal use of digitalis in treatment of patients who have congestive heart failure undoubtedly must be responsible to some degree for the frequency of T wave alterations; but this would hold true, of course, as much for one group as it would for the other.

As there is a preponderance of older persons among those who succumbed within the first five years after the onset of cardiac decompensation, and as there was among this group a higher incidence of coronary and hypertensive heart disease (the commonest cause of

T wave inversion and of conduction disturbances of all kinds), these differences in electrocardiographic findings lose their significance to some extent in assessing the prognosis of patients who have reached the stage of congestive heart failure. Auricular fibrillation, it will be noted, occurred much more frequently in the group

patients suffering from rheumatic heart disease, the majority of whom had mitral stenosis.

Among those whose clinical course was more favorable after cardiac compensation had been restored, it will be illustrated presently that all types of gross electrocardiographic abnormalities and all degrees of cardiac

TABLE 3—*The Status of Patients Who Were Still Alive at the Completion of the Survey*

Years After First Failure	Case Number	Age,* Years, and Sex	Cause	Heart Size	Electrocardiogram	Cardiac Reserve	Treatment	Comments
4	1	49 ♀	Mitral stenosis	17 cm.	Right ventricular preponderance	Compensated ..	Moderate restriction and digitalis	Had severe anemia (controlled)
	2	62 ♀	Hypertension	17 cm	Auricular fibrillation, inverted T 1, 2, 3	Compensated most of time	Restricted program, periodic salyrgan, digitalis	
5	3	55 ♂	Mitral stenosis	Enlarged, 1†	Auricular fibrillation	Compensated....	Moderate restriction, digitalis	
	4	70 ♂	Coronary sclerosis	Normal	Diphase T 2, 3	Compensated...	Moderate restriction	
6	5	60 ♂	Obesity, coronary disease	17.5 cm	Left ventricular preponderance, inverted T 1	Compensated.	Moderate restriction, program well supervised	Weighted 300 lb. at time of failure
	6	65 ♀	Hypertension	18.5 cm	Auricular fibrillation, left ventricular preponderance	Compensated....	Moderate restriction, digitalis	
7	7	41 ♀	Mitral stenosis	Enlarged, 3	Auricular fibrillation, right ventricular preponderance	Decompensated at intervals	Salyrgan regularly, digitalis and oral diuretics	
	8	61 ♀	Hypertension, mitral stenosis	Enlarged, 3	Right ventricular preponderance	Compensated	Under supervision of family physician	Was obese
	9	72 ♀	Hypertension, hyperthyroidism	Enlarged, 2.3	Auricular fibrillation	Decompensated at intervals	Salyrgan at regular intervals, restricted activities	Thyroidectomy done at the age of 65 years
8	10	62 ♂	Aortic regurgitation	Enlarged, 3	Inverted T 1, 2	Decompensated at intervals	Restricted activity, digitalis	Serologic reaction for syphilis positive
	11	45 ♂	Adhesive pericarditis	Enlarged, 2	Diphase T 1, 2, 3	Compensated ..	Restricted activity	
	12	77 ♀	Hypertension, hyperthyroidism	Enlarged, 2	Auricular fibrillation, left ventricular preponderance	Recurrent failure	Much restriction	Thyroidectomy at the age of 69 years
9	13	74 ♀	Coronary disease, hyperthyroidism	Enlarged, 3	Left ventricular preponderance, bundle branch block	Compensated since thyroidectomy	Only moderate restriction	Thyroidectomy at the age of 65 years
10	14	62 ♂	Hypertension	Enlarged, 3	Left ventricular preponderance	Compensated ...	Restricted activity	Weighted 215 lb., weight reduced to 180 lb.
	15	60 ♂	Hypertension	Normal	Negative	Decompensated at times	Restrictions, digitalis	Was in bed for a long time (fractured leg)
	16	63 ♂	Hypertension	19.5 cm	Auricular fibrillation, inverted T 1	Compensated	Restrictions, digitalis	Weighted 215 lb.
11	17	50 ♀	Mitral stenosis, hyperthyroidism	Enlarged, 3	Auricular fibrillation, right ventricular preponderance	Compensated. ..	Considerable restrictions, digitalis	Thyroidectomy at the age of 37 years
	18	47 ♂	Mitral stenosis	Enlarged, 3	Auricular fibrillation	Frequently decompensated	Much restriction and frequent salyrgan injections	Apparently co-operates poorly
	19	38 ♀	Mitral stenosis, hypertension	Enlarged, 3	Auricular fibrillation, inverted T 2, 3	Compensated ..	Visits heart clinic regularly, digitalis	Thyroidectomy at the age of 27 years
12	20	52 ♂	Pick's disease	?	Right ventricular preponderance, inverted T 2, 3	Is in chronic failure	Being treated for failure continuously	
	21	51 ♀	Mitral stenosis, hypertension	Enlarged, 3	Auricular fibrillation, right ventricular preponderance	Recurrent failure	Restrictions, salyrgan, digitalis	
13	22	60 ♂	Coronary sclerosis	Not enlarged	Left ventricular preponderance, diphase T 1, 2	Compensated	Much restrictions, digitalis

that survived for five years or more after the onset of cardiac decompensation, a fact again which must not be construed as indicative of a more favorable clinical course for patients whose auricles fibrillate than for those who maintain a sinus rhythm. The explanation is more likely to be found in the fact that there was a preponderance in this group of relatively younger

hypertrophy were found to exist at the time when the patients were first treated for congestive heart failure.

The immediate response to treatment and the degree of cardiac decompensation may be misleading criteria at times in reflecting the future progress of the patient who has congestive heart failure. Though many patients are easily rendered fluid free, recurrence of cardiac

failure may be equally prompt, and, conversely, an initially slow response to treatment may be followed eventually by surprisingly good restoration of compensation.

THE STATUS OF PATIENTS STILL ALIVE AT THE COMPLETION OF THE SURVEY

The data regarding the 22 patients who were alive at the completion of the survey have been summarized in table 3. Attention is drawn to the following findings:

1. There is a high incidence of rheumatic mitral stenosis. It is to be noted that there was but one case of aortic regurgitation in the group. At the time of the original examination of this patient a diagnosis of syphilitic aortitis was made on the basis of a positive serologic reaction for syphilis. The probability that this was a rheumatic aortic lesion occurring in a patient who coincidentally had syphilis must be entertained strongly. In the entire group of 150 patients studied, the diagnosis of rheumatic aortic disease was made in 7 instances (not including the aforementioned case). Only one of these patients lived beyond two years after the onset of congestive heart failure. This particular patient, who was noted to have a complete auriculo-ventricular dissociation and a moderately enlarged heart, lived six years after the first break in cardiac compensation. A study of 228 cases of calcareous aortic stenosis indicated clearly the late onset of symptoms in aortic disease but the poor response to treatment after the heart actually has failed.

2. The sexes are equally represented among this group of patients who were still living at the time the survey was completed. It is to be recalled that the proportion of men to women in the entire group was 5:2.

3. In almost every case there is cardiac enlargement, varying from moderate to gross hypertrophy. This fact indicates again that one's sense of values referable to cardiac size as a prognostic criterion is modified somewhat after heart failure occurs.

4. In 50 per cent of the cases the hearts were fibrillating at the time when the patients were being treated for heart failure, and gross electrocardiographic abnormalities existed in almost every case.

5. Only a few patients were living a life which might approximate normal; the very prolongation of life seems to depend on systematic supervision of the patient and on an indefinite extension of a therapeutic program intended to meet recurrences of cardiac failure when they occur.

6. The unburdening of extracardiac loads such as anemia, hyperthyroidism and obesity (and, one might add, though not represented in this group, avitaminosis and myxedema) may aid considerably in restoring cardiac reserve to an already crippled heart.

COMMENT

The occurrence of congestive heart failure regardless of the cause represents, with few exceptions, a serious phase of heart disease. The exceptions refer to those instances in which it is possible to relieve the load which the cardiac apparatus is carrying, as in the correction of severe anemia, or avitaminosis, the control of hyperthyroidism or of myxedema and the reduc-

tion of the peripheral capillary bed—specifically by reduction of the weight of obese patients.

The withdrawal of a patient from an occupation involving much physical activity to a more sedentary mode of life is an approximation to the procedures enumerated but is less effective, since in the majority of cases of congestive heart failure the process underlying the cardiac decompensation results from an irreversible and a progressive disease. A heavy mortality rate from year to year is the rule in patients whose hearts have once been decompensated. Mitral disease has a tendency to cause heart failure relatively early in life, but the reestablishment of compensation usually can be accomplished at times after repeated failures in fact. Aortic disease of rheumatic origin has a tendency to cause heart failure relatively later in life, but the maintenance of compensation once restored is seldom lasting. Similarly, congestive heart failure due to syphilitic aortic disease has a poor prognosis.

Hypertensive and coronary disease may follow either tendency after the first break in cardiac compensation. Malignant hypertension has a poor prognosis even independent of cardiac failure. Similarly, acute myocardial infarction tends to increase the gravity of coronary sclerosis. It is known further that the coexistence of pulmonary disease militates against recovery from congestive heart failure.

The presence of cardiac enlargement seems clearly to favor the onset of cardiac decompensation; yet some patients who have considerable cardiac hypertrophy seem to do as well (or as poorly) as do many with lesser degrees of enlargement. The same remarks as apply to cardiac enlargement could apply readily to patients whose auricles fibrillate. The observation has been made³ that patients in congestive heart failure respond more satisfactorily to treatment if auricular fibrillation is also present, regardless of the cause, than if it is not present, and this study seems to bear this observation out. Electrocardiographic findings are of little help in the prognosis of congestive heart failure. They conform to the disease responsible for the cardiac decompensation rather than to its gravity. The initial response to treatment does not reflect necessarily any reliable prognostic trend.

If we can learn a lesson from those patients who have continued to live after their hearts have once decompensated, it is simply that recurrences of failure must be not only anticipated as a possibility but actually expected, for the prolongation of life seems to depend on a systematic therapeutic program which calls for close cooperation between the patient and his physician.

The risk of administering an injection of a mercurial diuretic agent when it is perhaps not necessary is far less than the risk of allowing congestive failure to proceed from its earliest stages (when clinical evidences are still lacking). Many patients learn to recognize subjectively the earlier symptoms of return of heart failure; others are warned of oncoming decompensation by a daily increase in their weight. The choice of drugs in the treatment of congestive heart failure and in the maintenance of compensation is a matter of individualization, but digitalis seldom can be left out of the therapeutic program of any patient who has or has had congestive heart failure, regardless of its cause.

WAR INJURIES TO THE HEAD

TREATMENT OF PENETRATING WOUNDS

RALPH B. CLOWARD, M.D.

HONOLULU, HAWAII

As a result of the bombing of Hawaii on Dec. 7, 1941 the opportunity was given to study and operate on a large number of patients with neurosurgical injuries.¹ This communication is a report of experience in the treatment of penetrating wounds of the head as seen among the first American casualties of the present war.

Nearly all these wounds were compound depressed fractures of the skull produced by fragments of shrapnel which varied in size from thin flat pieces less than 1 cm. across (fig. 3) to large, heavy, irregular chunks of steel 3.5 to 4 cm. wide and 0.5 to 1 cm. in thickness (fig. 1). The larger pieces of metal all had extremely sharp, jagged points, which ripped great irregular holes in the tissues of the head through which they passed. There were no round smooth bullets found in the group of patients treated.

The nature of the wound thus produced depended on the size of the missile and its position when making contact with the head. Some scalp wounds were so small as to be almost missed on casual examination. One such patient had a small wound in his forehead which appeared to be nothing more than a scratch. It was not picked up as a penetrating wound until twenty-four hours later, when roentgenograms of the skull revealed a metallic foreign body about 1 cm. in diameter and 1 to 2 mm. in thickness deep in the opposite frontal lobe (fig. 3). This missile had obviously struck the head on edge. The large wounds in the scalp were jagged, irregular defects with multiple radiating lacerations and considerable destruction of tissue.

Injuries to the skull by these missiles were interesting. The metallic fragments were apparently all traveling at high speed, as the defects produced in the skull were uniformly circumscribed holes (figs. 2, 3 and 4). No long linear fracture lines radiating from the point of entry of the foreign body were seen in any of the fractures. The smaller metal fragments usually made correspondingly small holes in the outer table of the skull, whereas the hole found in the inner table was many times larger than the missile. The shattered bone fragments were carried deep into the brain, lacerating cortical vessels and brain substance over a much wider area than what one would suspect from the size of the penetrating missile. The more extensive injuries to the head in which large portions of the skull were carried away or large pieces of bone driven deep into the brain were obviously fatal injuries. These patients were moribund on admission, and no attempt was made to treat them surgically.

The injury to the brain and its coverings was found as a rule to be much more extensive than one would anticipate from either the size of the foreign body or the condition of the patient. Large gaping defects were always found in the dura mater, having been made not only by the penetrating object but also by the fractured pieces of bone carried in with it. Cortical and subcortical vessels were torn, resulting in subarachnoid hemorrhages, some of which reached the proportions of small hematomas at the site of the injury. Hematomas of various sizes were often found deep in the

white matter of the hemispheres along the tract of the foreign body. In the larger compound wounds, by the time the patient reached the operating room, liquefied cerebral tissue and cerebrospinal fluid were always found herniating through the defect in the skin.

TREATMENT

Treatment of wounds to the head, like traumatic wounds elsewhere, is directed toward (1) restoring to normal as near as possible the injured tissues and (2) preventing complications which may arise secondary to the injury and result in disability, deformity or death.

The preliminary treatment, prior to operation, is extremely important. When the wounded person is first seen at the receiving station the hair about the wound in the head is clipped widely with the hair clippers. The edges of the lacerated wounds are cleansed with soap and water. Any large bleeding vessels in the lacerated scalp are stopped with a hemostat, local pressure or a piece of rubber tubing about the head. A temporary dressing is then applied after the wound has

Fig. 1.—Example of the type of sharp, irregular pieces of shrapnel found in war wounds; $\times 2$.

been filled with powder of one of the sulfonamide drugs. Unless the patient has extensive painful wounds elsewhere, the routine use of morphine is contraindicated.

On admission to the hospital the patients are first examined neurologically and given tetanus antitoxin, and roentgenograms of the skull are taken, stereoscopic views whenever possible. If the patient shows signs of shock, this is first treated with intravenous saline solution, blood plasma or whole blood when the latter can be obtained. After shock has been treated the operation is not delayed any longer than necessary. Because of the large number of cases treated, it was necessary in many instances to delay as long as twenty-four to thirty-six hours after the injury. No infection was encountered in any of these cases in which the preliminary treatment described of cleansing the wound and applying the sulfonamide powder was employed.

As a local anesthetic 2 per cent procaine hydrochloride was found adequate for the majority of our patients, since they were conscious and cooperative. Restless and uncooperative patients can be given avertin with any-

1. It is not permissible to report the number of persons treated at this time

lene hydrate supplemented with intravenous pentothal sodium.

In the treatment of the scalp wounds a wide area circumscribing the wound is painted with iodine and a local circular block anesthesia induced. The wound can then be scrubbed and cleansed without pain to the

Fig 2.—Postoperative appearance of skull from which the shrapnel shown in figure 1 was removed. A silver clip lying beneath the middle fossa of the skull indicates the depth of penetration (arrow)

patient. Large quantities of sterile water and green soap and a mild antiseptic are used. All jagged irregular edges about the wound are cut away. It was found that large defects in the scalp, up to 4 cm., could be approximated and closed tightly by adequate undermining. A fusiform incision is made around the wound. After the scalp has been slid so that the edges are approximated, the tension on the closure sutures can be relieved by placing one or two anchor sutures 1 cm. or so back from the incision edge. Such a suture passes through the scalp in its new position and beneath the periosteum. It is tied on the outside over a small roll of gauze. All scalp wounds are closed without drains by two layers of black silk. Larger scalp wounds are closed by the method of Sargent²; i. e., undercutting the outer layer of the scalp and making a new incision on either side of the wound so that it can be approximated. Two raw crescent shaped areas are thus exposed, but these rapidly granulate in and epithelize.

When the penetrating hole in the skull is small, one can obtain adequate exposure for the treatment of the underlying structures by rongeur away the jagged edges of bone and enlarging the defect. Larger holes in the skull, however, with more extensive damage to the dura mater and brain, require more exposure and for these a small bone flap is elevated along one side of the hole in the skull. The exposure of the bone flap in the larger wounds is important also in order to obtain a large piece of periosteum from the skull to be used in the repair of the dura mater.

The defects in the dura mater, like those in the scalp, are usually jagged, irregular holes. They are always larger than the scalp wound, owing to tearing by the fractured fragments of skull in addition to the missile. The edges of the dural defects are debrided of the small irregular tags to obtain straight, clean edges. The cautery for small bleeders on these edges is avoided, hemostasis being obtained by mosquito clamps. All dural defects are closed tightly with

the patch obtained from the periosteum of the overlying skull. The importance of a tight closure of the dura mater with such a patch cannot be overemphasized, particularly when the wound passes through any of the paranasal sinuses. One can thus prevent the formation of a fistula with cerebrospinal fluid draining through the nose and the possible development of meningitis from the adjacent potentially infected sinuses.

One of our patients was struck between the eyes with a large jagged piece of steel (fig. 1). The missile passed directly through the frontal sinus, and buried itself in the skull to a depth of 9 cm. (fig. 2). In its pathway the roof of the left and medial wall of the right orbit and the cribriform plate were carried away. The ethmoid and sphenoid sinuses were destroyed. The contents of the left orbit, including the optic nerve, were torn. A hole measuring 4 by 6.5 cm. was opened up in the dura mater covering the inferior surface of both frontal lobes. A large periosteal patch was removed from the bone flap and this extensive defect closed tightly by means of interrupted black silk sutures. The wound was filled with sulfanilamide powder and closed without drains. No cerebrospinal fluid fistula nor infection developed, and the patient is recovering.

A thorough débridement and cleansing of the tract of the missile through the brain is perhaps the most important part of the operative procedure. Hair, dirt, grass and fragments of fractured bone were found to have been carried into the brain by the penetrating missile. The blood clots along the tract and the damaged brain are removed with the suction. The fragments of bone and the foreign bodies are picked out of the wound and the sinus tracts then irrigated with copious quantities of warm sterile saline solution.

Some surgeons recommend palpation of the tract with the finger. This can be done when the wound is larger than the finger. The smaller tracts are best explored by the method advocated by Dr. Harvey

Fig 3.—Foreign body in right cerebral hemisphere. Arrow indicates point of entry on left. The patient died forty eight hours later of an extensive subdural hemorrhage from a vessel torn in the falx

Cushing; i. e., palpating the depths of the wound with a soft rubber catheter.

When an inspection of the tract in the brain shows that it is completely free from foreign material and all bleeding points have been arrested, the tract is filled with sulfanilamide powder before the wound is closed. Although none of our patients have been followed for a sufficient time to make a statement as to the post-

2. Mitchiner, P. H., and Cowell, E. M.: Air Raid. XI. Wounds of Head, Spine and Peripheral Nerves. *Lancet* 1: 639-645, 1939.

operative complications, it seems from reports of others³ that, if the aforementioned treatment is carried out, the possibility of subsequent formation of a brain abscess or meningitis will be avoided.

The question arises as to whether or not the metallic foreign bodies should be removed from the brain or left in. In all these cases in which the missile was at all accessible it was removed. However, in instances in which the metal was small and had penetrated the brain to a great depth and it was obvious that greater damage to the brain would be produced by attempting to recover it, the foreign body was not removed. In 1 such case (fig. 3) the shrapnel entered the head in the frontal region high on the left side and passed directly through the left frontal lobe and lodged about 2 cm. from the midline on the right side. Obviously no attempt was made to remove this foreign body, although the tract in the brain through which it passed and the dura and skull were treated as described. The chief danger in leaving metallic foreign bodies in the brain is the development of convulsions at a later date. It has been said that 5 to 50 per cent of persons with bullets in their brain will eventually develop epilepsy. These attacks may not begin for six months or more after the injury. The use of electromagnets for the recovery of these bodies has been reported.⁴ This method may be of value in selected cases.

The postoperative care of these patients consists chiefly of absolute bed rest. Pain is controlled with acetylsalicylic acid and barbiturates. All patients are given chemotherapy for a week or ten days or longer after operation depending on the temperature reaction and extent of injury. The routine use of an anticonvulsive drug in adequate doses is recommended. Soluble phenobarbital 0.065 Gm. three times a day was used. The patients are strongly advised to continue the drug for a period of at least one year after the injury.

Intravenous hypertonic solutions were found unnecessary in these cases. Lumbar punctures were done only when persistent signs of subarachnoid hemorrhage appeared.

No postoperative complications were encountered in the patients operated on within the first forty-eight hours, with one exception. This patient died suddenly the day after operation of an extensive subdural hemorrhage (fig. 3). Another patient, seen in a small rural hospital four and a half days after his injury, died of meningitis (fig. 4). When postoperative infections occur it may become necessary to reopen and pack the wound for drainage. The gauze used for packing is filled with sulfanilamide powder.

PHYSIOLOGIC OBSERVATIONS

Some interesting observations were made on the physiology of this type of wounds in the head. Few of the patients with penetrating wounds of the brain were brought to the receiving station in an unconscious state. The majority of them had not even been unconscious but were able to recall everything that had transpired from the time they were hit until they

arrived at the hospital. This was a most surprising fact to the doctors who saw these cases. Patients with large gaping wounds in the frontal areas with considerable quantities of cerebral tissue oozing from the wounds were found to be conscious, cooperative, rational and able to give their identification. Most of

Fig. 4.—Irregular piece of shrapnel lying partly in lateral ventricle. Note air in temporal horn of ventricle and about hole in skull. This wound was infected.

the patients were in a state of mild shock with lowered blood pressure and pulse rates from 90 to 110. Aside from this the normal physiologic functions did not appear to be altered materially. These findings applied only to the penetrating wounds of the head. Patients whose lesions had been produced by a large object striking the head, or vice versa, carrying away large sections of brain and skull or producing extensive depressions, were obviously deeply unconscious. They showed slow, irregular heaving respiration, weak, rapid, thrready pulse and elevated blood pressure. All patients admitted in this condition died within a few minutes to twelve hours after admission to the hospital.

The observations on the state of consciousness of patients with penetrating wounds of the brain is in accord with the present accepted theory of the physiology of the loss of consciousness from head injuries. The experimental work of Walker,⁵ Denny-Brown and Russel⁶ and others has shown that loss of consciousness associated with injury to the head is primarily the result of microscopic changes in nerve cells of the brain resulting from physical acceleration of these cells. Walker cites the case of a man lying under his automobile with his head resting on the ground. When the car jack slipped, his head was crushed between the car and the ground and an extensive fracture of the skull produced. The patient did not lose consciousness even for a second. The opposite condition is that of a person who walks into a door, striking his head. He falls to the floor, is dazed for several minutes, develops a violent headache, vomits and is extremely ill. He shows all the usual signs of a cerebral concussion. In the first case the brain was not affected by inertia, having been held in a fixed position when struck. The patient did not lose consciousness. In the second case the brain was set into motion by the blow, and the damaging effect on the brain produced by the physical acceleration of the nerve cells was evident by the illness which followed.

Other physiologic conditions which have been said to contribute or cause the loss of consciousness in head

injuries are loss of blood, damage to brain substance itself and cerebral anemia. All three of these conditions were seen in the majority of these patients. There was considerable loss of blood in almost all cases due to wounds in other parts of the body, some of which were very extensive, such as the loss of one or more extremities. With this loss of blood a cerebral anemia was certainly present as part of the condition of shock which these patients showed. The damage to brain tissue was as a rule rather extensive, yet in these patients consciousness was not impaired.

It is my impression that the reason these patients did not lose consciousness from their injury was the fact that the force applied to the head was concentrated in such a small area compared to the entire area of the skull that generalized acceleration of the brain was not produced. The speed with which the objects were traveling was so great that the head was struck, perforated and penetrated before the brain as a whole had time to be set into motion. The absence of linear fractures of the skull around the point of entrance is evidence of the high speed the missiles were traveling. The threshold of acceleration necessary to produce unconsciousness, as shown by Denny-Brown and Russel,⁶ is the change of speed of the head from 0 to 23 feet per second. It would seem impossible for a small missile striking the head at high speed to set the entire head in motion at this rate.

LITERATURE

While the literature on the treatment of closed craniocerebral injuries has been voluminous, there has been surprisingly little reference to penetrating wounds of the brain in the period between the appearance of the medical records of the first world war and 1938. In the past three years (1938 to 1941) surgeons and neurosurgeons in almost every country of Europe and Asia have reported their experiences with this type of wound. Many reports have come out of Germany,⁷ France,⁸ England,⁹ Australia,¹⁰ Norway,¹¹ Italy¹² and even China.¹³ The low mortality rate reported by these authors shows the value of the modern methods of treatment of these wounds. The mortality of brain wounds in the early part of the first world war was over 60 per cent.¹⁴ Dr. Harvey Cushing lowered this figure to 28 per cent by improving the operative technique. The mortality rate of the second world war should be far below this figure, judging from these recent reports.

A few important points which most authors agree on in the treatment of penetrating wounds of the head may be mentioned: 1. The optimum time to operate is within six hours after the injury, but wounds which have gone untreated as long as forty-eight hours should be treated as fresh wounds and closed without drains, unless there is obvious infection. After forty-eight hours the wound is treated as a brain abscess with open drainage.¹⁵ 2. All metallic foreign bodies should be removed if possible, because they lead to secondary abscess and epilepsy. 3. The defect in the dura mater should be closed completely in clean wounds with fascia or periosteal grafts. 4. Generous use of sulfanilamide not only in the scalp and skull wound but in the missile tract in the brain is recommended.¹⁶ Sulfanilamide is preferred because it has been found to be much more rapidly absorbed into the blood stream from an open wound than any of the other sulfonamide drugs.¹⁷

THE SOLDIER'S IRRITABLE HEART

CERTAIN OBSERVATIONS OF INTEREST

PAUL D. WHITE, M.D.

BOSTON

Much has been written concerning the irritable heart of soldiers, the best by DaCosta in 1871 and a good deal of varied interest in the last two decades since the first world war. The chief type has been well described under various names, best known of which are neurocirculatory asthenia and effort syndrome. The fundamental cause, however, remains obscure, the types and variations are not well differentiated, and early recognition at the time of recruitment of persons prone to a disabling degree of the condition under the stress of heavy military service is sometimes far from easy. These problems still await solution.

Meanwhile there are points of immediate interest and importance about the condition that are inadequately recognized but should be helpful in the present military emergency. These I wish herewith briefly to present.

In the first place, true irritability of the heart as indicated by extrasystoles or paroxysmal tachycardia is not connected in any way with neurocirculatory asthenia except accidentally. In fact, most persons with the latter condition tend to have little arrhythmia of the heart. The nervous tachycardia so often present in neurocirculatory asthenia and in men being examined for entrance into military service tends actually to keep away extrasystoles. Cardiac arrhythmia may, however, easily induce a cardiac neurosis unless care is taken not to exaggerate its importance and unless steps are planned to try to eradicate it. Rarely may the fatigue from excessive arrhythmia help to induce neurocirculatory asthenia.

The next point also concerns definition. Neurocirculatory asthenia is not established as yet primarily

as a psychoneurosis, although such is at least a common complication. A cardiac or other neurosis may be present with none of the evidence of neurocirculatory asthenia, which is clinically a symptom complex resulting chiefly from fatigue and consisting of various combinations of palpitation, heartache, dyspnea (often sighing), faintness, easy fatigability, increased perspiration, tremor and nervousness, in whole or in part. Anxiety neuroses and hysteria may induce hyperventilation and secondary palpitation and faintness, and perhaps even the entire symptom complex of "neurocirculatory asthenia," but fatigue per se without any initial neurosis at all can apparently set off typical neurocirculatory asthenia. How much of a role anxiety neuroses and how much fatigue per se and how much their combination, or still other factors, have to do with the development of neurocirculatory asthenia, and whether it is to be adjudged a disorder of the vegetative nervous system to be set off by any one of a variety of causes, are not yet known. More studies of the relationship between these various conditions are needed, and such studies are actually now under way.

In the next place, the borderline between "neurocirculatory asthenia" and "neurasthenia" is apparently so wide, if any exists at all, that accurate statistics of the incidence of the former are at present impossible. It is certain, for example, that many cases of neurocirculatory asthenia are being designated as neurasthenia or anxiety or fatigue neurosis or even psychoneurosis or constitutional psychopathic inferiority in the examination of the draft for the army and in medical diagnoses and discharges of soldiers already in service. For the present, for the sake of clarity, there should be some attempt at more accurate definition or at least designation. If there is a psychoneurosis with symptoms of neurocirculatory asthenia, both conditions should be stated to be present, with emphasis on the one which is preponderant; if only one of the two conditions is present, the correct designation should be given. Neurocirculatory asthenia should not yet be called a psychoneurosis, or vice versa; it is hoped in the future, as stated, to have a clearer understanding of their relationship.

It is of interest that as yet there has been relatively little neurocirculatory asthenia in the American or even in the British army, partly because an attempt has been made to weed out possible candidates for the condition before enlistment and partly because the strain of actual combat duty in the British army has been as yet not heavy, except at Dunkerque and in Greece and Crete and now in North Africa. More will undoubtedly crop up when military operations become more extensive. Even the civilian population under heavy bombardment evidently suffered little from neurocirculatory asthenia.

And, finally, it has been found wise in England to treat the average run of the cases of neurocirculatory asthenia that have arisen in the armed forces as ordinary medical cases of fatigue without referring them to either cardiologist or psychiatrist, in this way avoiding overemphasis of either heart or mental state in the patient's mind. This seems a wise and sensible procedure.

Thus, for the time being at least, it is important to differentiate between the irritable heart with arrhythmia, neurocirculatory asthenia, and psychoneuroses.

Massachusetts General Hospital.

EARLY DIAGNOSIS AND PROPER
MANAGEMENT IN CERVICAL
CANCER

DANIEL G. MORTON, M.D.
SAN FRANCISCO

The most definite fact known regarding cancer is that with modern methods of treatment a reasonable hope of cure is absolutely dependent on an early diagnosis. It is a source of great satisfaction that many thousands of men and women are living in the United States today who were treated for cancer more than five years ago. On the other side of the ledger is the depressing realization that these thousands represent scarcely one fourth of the total number treated. The explanation for this relatively small salvage lies principally in the fact that the majority of persons seek treatment only after the disease is well advanced. There can be no doubt of this explanation, for there is ample proof of the relative hopelessness of the disease when it is advanced and the good results obtainable when it is early, in the published reports of the world. By way of illustration, the figures from the University of California Hospital on cancer of the uterine cervix are entirely representative (table

TABLE 1.—Five Year Survival Rates: 432 Primary Carcinomas of the Cervix at University of California Hospital (1916-Dec. 31, 1935)

Stage	Cases	Percentage	Number Surviving 5+ Years	Percentage
1 } Early.....	46 }	23.4	37	80.4
2 }	77 }		31	40.3
3 } Advanced.....	211 }	71.6	50	23.2
4 }	98 }		4	4.1
	432		122	28.2

1). They show that better than one half of the patients with early lesions survived for more than five years while less than one fifth of the women with advanced growths survived the five year period.

These figures also show that two thirds of the women seeking treatment for cervical cancer had advanced growths. It seems clear, then, that late diagnosis is the chief limiting factor in achieving significant improvement in results, and the most important clinical problem regarding cancer today is making earlier diagnoses.

Having considered briefly the importance of early diagnosis, I shall turn my attention to the methods of diagnosis and the proper management of cervical cancer. The first factor involved in making an early diagnosis is prompt attention to the initial symptoms. Unfortunately, up to the present there has been delay in such attention in the majority of cases. The delay has usually been attributable to the patient's ignorance or neglect, but too frequently it has been attributable to the physician also. An analysis of the 432 primary five year cases at the University of California revealed that only 29 patients sought medical attention immediately or within two weeks of the appearance of symptoms, while 278 delayed for more than four months. There were 54 instances of delay attributable to the physician, as

This study was made possible by a grant from the Medical Reserve Fund.
From the Department of Obstetrics and Gynecology, University of California Hospital.
Read before the Section on Obstetrics and Gynecology at the Ninety-Second Annual Session of the American Medical Association, Cleveland, June 4, 1941.

well as 58 instances of incorrect diagnosis. The total duration of symptoms for all patients when added up was equivalent to three hundred and eleven years, of which the physician was responsible for 11.1 per cent, or thirty-four years. The final result: an average duration of symptoms of eight and seven-tenths months. Yet prompt recognition of warning symptoms would mean a tremendous improvement in the prognosis, without regard to other factors, such as the anatomic extent of the growth or the form of treatment. The accompanying chart illustrates graphically the five year survival results correlated with the duration of symptoms. It is seen that the earlier the symptoms were recognized (provided not more than six months had elapsed) the higher was the percentage of cure. For example, for those whose symptoms were of two months' duration or less the five year survival was 42.4 per cent, which is in striking contrast with the 28.2 per cent salvage for the whole series.

These facts controvert the idea that when symptoms arise the disease is always advanced and emphasize the value of immediate attention to the warning signs. Table 2 shows that when symptoms were of short duration a much higher proportion of the cases were in the early stage than was the case for the whole series.

As to the patient herself, the occasion for delay is usually ignorance of the significance of bleeding, which is the initial symptom in the vast majority of cases (75 per cent in this series). A thin, watery or foul discharge, either coming on initially or representing a change from a mucoid discharge, is the first symptom in a smaller number (15 per cent), while in a few cases (10 per cent) there are no significant symptoms. The bleeding is usually intermittent and of small amount, appearing between the periods often only in response to unusual activity, intercourse or other vaginal manipulation. Patients frequently consider it some abnormality of menstruation and by popular misconception have been led to regard such bleeding as a normal accompaniment of the approaching menopause. When bleeding starts after the menopause it is often spoken of as a return of menstruation. The only remedy for these misconceptions is popular lay education, a subject which cannot be discussed more fully at this time.

Quite within our powers to correct, however, is the physician's part in the picture. Sad indeed is it when we are told by patients that they were not examined

tion is constantly presenting itself to every practitioner who deals with women.

A second possible factor in early diagnosis is periodic examination. Its value has yet to be proved conclusively, but theoretically periodic examination, every six to twelve months during the age of greatest incidence of cervical cancer, say from 35 to 50, would result in the discovery of an occasional early growth. We as physicians should advocate it to our patients much more militantly than we do.

TABLE 2.—Division of Cases into Stages of Advancement

Stage	Whole Series		Those Having Had Symptoms for Two Months or Less	
	Cases	Percentage	Cases	Percentage
1.. ..	46	10.6	26	24.5
2. . . .	77	17.8	25	23.6
3.	211	48.8	42	39.6
4. ..	98	22.8	13	12.3
	432		106	

The third important factor is the ability to recognize cervical cancer when we see it, not always an easy task in its early stages. The well developed growth rarely confuses; these lesions are either everting cauliflower masses which are friable and bleed easily on manipulation or they are the ulcerative or indurative type in which one frequently finds a crater lined with grayish white necrotic material. The vaginal fornices are often partially or completely obliterated, and the margins of the growth are hard and lumpy. Occasionally the cervical mucosa remains intact and the form of the cervix is preserved, yet the tissue is hard and fixed. Parametrial induration may or may not be present. Much more difficult to recognize are those lesions which are small and well confined to the cervix, or those which are hidden by a smooth, well preserved external os. The early lesion may appear as a shallow ulcer with a slightly raised firm border, in which case it is difficult to differentiate it from an ordinary erosion; or one may see only an irregular beading of the surface. Touching with an applicator frequently causes bleeding. In case of doubt, the only safe plan is to perform a biopsy, for no man lives who can correctly diagnose every early lesion by inspection with the naked eye alone. In this series there were 18 instances of accidental diagnosis.

Aids in the diagnosis of early carcinomatous changes are Schiller's test and the colposcope. The former is performed by instilling into the vagina a sufficient quantity of modified compound solution of iodine (formula: iodine 1 part, potassium iodide 2 parts, water 300 parts) to cover the cervix completely. After five minutes the solution is sponged out and the cervix reinspected. The normal mucosa stains a dark mahogany; eroded areas fail to stain at all; when carcinoma exists the mucosa appears dead white, and usually there is a distinct, well defined border between the normal and abnormal areas. This test depends on the presence of glycogen in the normal epithelial cells and on its absence in carcinoma cells. When positive, it is very suggestive and is an aid in pointing out areas to be taken for biopsy. When the test gives a negative result the absence of cancer should not be assumed. Occasionally one encounters false positives also. If the limitations of the test are recognized it can be of value, but the results can never be regarded as definitely diagnostic. The colposcope, which is merely an instru-

Percentage of patients surviving more than five years whose duration of symptoms was one month or less, two months or less and so on

when they consulted their physicians on account of bleeding but were informed that "It is only the menopause." There were at least 16 such cases in this series. Of every patient with bleeding, the absolute necessity for vaginal examination and further investigation, if the cause is not immediately clear, cannot be overemphasized. If nothing is found the physician has an excellent opportunity to apprise his patient of the symptoms which demand immediate investigation should they arise at a later date. The word "cancer" need not even be mentioned. This opportunity for individual educa-

ment for bringing the surface of the cervix into greater magnification under intense illumination, falls into much the same category. To be of value, this instrument requires great usage in order that one may learn to recognize the abnormal as distinguished from the normal. Here, too, the results can be regarded as suggestive only.

In the final analysis, the most important procedure of all in confirming or excluding a diagnosis of cancer is biopsy. A biopsy is absolutely demanded in every suspicious case. The biopsy is not without its drawbacks, however, and should not be performed indiscriminately. A cut made into a suspicious cervix, which is usually infected as well, occasionally leads to a pelvic cellulitis and even death. We have had such cases. While the matter is as yet unproved, the cut may also open the lymphatics to the spread of cancer. Because of this possibility, if cancer is likely to be present it is best not to perform a biopsy except under conditions which will permit immediate treatment should the diagnosis be confirmed.

Lastly is the problem of correctly interpreting the microscopic picture. Generally the picture is quite clearly cancer or not cancer, but occasionally one

Clinical diagnosis, on the other hand, is every man's problem, and I am convinced that much can be done to promote earlier and more accurate diagnoses. If results in this disease are to be improved, the lesson is this: 1. Every physician must be keenly aware of the possible significance of bleeding or abnormal discharge, particularly when it arises between periods or after the menopause. When such symptoms appear, a vaginal examination including inspection of the cervix is imperative; biopsy is indicated if the appearance of the cervix is not clearly innocent. When a suspicion of cancer has proved groundless, a warning of significant symptoms should be given. 2. Every physician should encourage periodic pelvic examination during the years of greatest cancer incidence. 3. Every physician should see that a biopsy is taken of all suspicious lesions of the cervix, preferably under circumstances which will permit immediate treatment should cancer prove to be present. 4. Every physician should see that patients with cancer get the benefit of the best facilities and knowledge in treatment.

ABSTRACT OF DISCUSSION

DR. RALPH E. CAMPBELL, Madison, Wis.: Dr. Morton has published several reports relative to carcinoma of the cervix which have added significantly to the literature. This report from the University of California Hospital adds another important contribution to the early diagnosis and proper management in cervical carcinoma. Table 1 shows, relative to patients surviving five years after treatment, that it is most important that the cancer of the cervix be seen in its early stages rather than in the advanced stages to obtain satisfactory therapeutic results. The chart shows that patients with long standing symptoms show favorable five year survival figures proportionate to the length of time they have presented symptoms. From the standpoint of both prognosis and treatment these analyses are important. Table 1 and the chart presented real problematic discussions. It would seem that the question of early diagnosis in part depends on when the patient appears before the physician for examination, and this in many instances depends on lay education. Too frequently women ignore such symptoms as a vaginal discharge and irregular bleeding. This may be due to ignorance or ill advice from other women. Some women fail to appear for examination because of the fear of cancer, not realizing that the disease is curable. It has been common thought with women that irregular bleeding near the menopause is a normal accompaniment of this change. Occasionally women believe that postmenopausal bleeding is the reappearance of the menstrual function and also attribute no significance to increased vaginal secretions. Unfortunately, some physicians play a part in giving these erroneous ideas to their patients; they may further inculpate themselves by omitting a pelvic examination or by performing an incomplete pelvic examination without speculum visualization. At the same time medical treatment, such as ergot or other preparations, may be instituted which is hazardous from the standpoint of the patient. The foregoing emphasizes the importance of both lay education and postgraduate medical education. The Federated Women's Clubs have accomplished a great deal through their recent lay education project on cancer. In a lay program it should be emphasized that all important are examinations of women at least once or twice a year during the period of sexual activity or child bearing age. This will lead to the detection of irritative lesions and their eradication, which is most important in the prophylaxis of cancer as well as the early diagnosis and treatment of this disease. There is no substitute for the biopsy in the diagnosis of cancer of the cervix.

DR. GEORGE GRAY WARD, New York: There is no question that failure to investigate all cases of bleeding in women, however trivial, has much to do with the fact that so many cases of cancer go far too long before they come to adequate treatment. This carelessness may be largely put down to the fact that biopsy is not resorted to as frequently as it should be. I should like to call attention to the frequency of carcinoma

encounters a significant degree of epidermization which is confusing and is frequently misdiagnosed cancer. Well defined degrees of epidermization are rather commonly seen in cervical polyps. Thus a pathologist who is familiar with the varying pictures found in the cervix is essential if correct diagnoses are to be arrived at.

In my opinion, cancer should be regarded as a special disease and its management should be entrusted to those who are properly equipped in education, experience and physical facilities or to institutions dedicated to this end. A combination of high voltage roentgen therapy and radium therapy is the treatment of choice in the vast majority of cases, yet it is rarely possible to provide proper radiation or adequate surgery casually. Some of the results of casual treatment culled from our group of stage 5 or recurrent cases are shown in table 3.

It seems clear that cervical cancer, in fact cancer in general, presents a specialized problem. The results are not good at best, and when the treatment is incomplete or poorly conceived the results are terribly poor. Patients deserve the best chance of cure that modern methods can offer, and this chance is available to them only when they can have the advantage of the best knowledge and the best equipment. Rarely is the general practitioner so equipped, and often this is true of the gynecologist also. It becomes a matter of conscience as to whether a physician is or is not properly qualified.

associated with fibroids. As a result of that condition a great many women have been subjected to a supravaginal hysterectomy without, first, adequate investigation as to the nature of the condition that may be present in the cervix. Often an erosion which may be a carcinoma is simply regarded as an erosion, and a supravaginal hysterectomy is done; later carcinoma develops in the stump of the cervix. Stump cancer is a frequent condition. In my clinic at the Woman's Hospital in New York, in some 900 cases of carcinoma of the cervix, we have had 6.8 per cent cases of stump cancer. Some of those cases had occurred within the first year, and undoubtedly the carcinoma was present at the time of the hysterectomy that had been done elsewhere. The average of stump carcinoma is as high as 4 per cent, as has been shown by a number of workers. If a hysterectomy is to be done for a fibroid uterus, if supravaginal hysterectomy is considered, the cervix first should be carefully investigated, and, if necessary, a biopsy taken; if not, the cervix certainly should be watched by periodic examination. The results that have been obtained in the treating of stump cancer are fully as good as those in the average run of cases. We have been able to save about 40 per cent of patients with carcinoma of the stump.

DR. JOHN J. GILBRIDE, Philadelphia: When there is any suspicion of the presence of cancer of the uterus, the use of the curet is definitely contraindicated. A biopsy should be performed. Through the courtesy of others I am able to present these postmortem observations. Of 12 cases at autopsy local sepsis was present in 11, gross hemorrhage 4, rectovaginal fistula 2, vesicovaginal fistula 2, cancer nodules in the rectovaginal septum 2, unilateral pyelitis 2, bilateral pyelitis 2, unilateral ureteral obstruction 2, bilateral ureteral obstruction 2, right unilateral hydronephrosis 1.

DR. EMIL NOVAK, Baltimore: While recent years have seen some improvement in the results of radiotherapy, there are many who feel that we are approaching the limit of what may be expected from this method of treatment. For the present our chief hope of increasing the salvage rate in uterine cancer must lie in bringing to treatment a larger proportion of early cases. And when we speak of early cases we need not necessarily refer to the very early cases concerning which pathologists have had so much discussion, such as those of so-called preinvasive cancer. We would all be grateful enough for a substantially larger proportion of comparatively small, often obvious, and usually favorable cases in which, for example, the cancer is limited to an area of only a centimeter or so on one of the cervical lips. If a large proportion of our cases were of this sort, the statistics of cancer cure would be immeasurably improved. The work of such organizations as the American Society for the Control of Cancer is of the greatest importance, but the individual physician can and should carry on in his own practice an educational campaign of his own. Moreover, in our efforts to educate the public we should not forget that our own skirts are not altogether clean. There are few doctors so ignorant that they do not know that abnormal bleeding or discharge may mean cancer, and the delays chargeable to medical men are more commonly due to lack of thoroughness or to a peculiar apathetic detachment which allows the patient's diagnostic problem to drift along until it is too late. The physician should look on a suggestive case almost as if he were dealing with an acute disease, and he should not be content until the problem is settled decisively, as it can be in every case. If special methods of study, such as biopsy and microscopic examination, are necessary, as they so commonly are, he should not be satisfied with casually suggesting these to the patient, but he should put the full force of his influence into seeing that his recommendations are carried out. There are few women who will not take the proper steps if the importance of the problem is properly and tactfully presented. It is especially the early favorable cases which need this intensive approach, but in this group the rewards are apt to be large. Biopsy and microscopic examination constitute the sine qua non in the diagnosis of doubtful cases. Such adjuncts as colposcopy and the Schiller test I believe to be of only limited value. Such a test cannot possibly in itself make the diagnosis, and no sensible general practitioner would wish to assume the responsibility of deciding such an important question unless more accurate methods are utilized. The great-

est contribution he can make is to be on the alert for cases which on the basis of symptoms or examination are at least suggestive, and to see that the patient receives proper diagnosis and treatment.

DR. CHARLES EDWIN GALLOWAY, Evanston, Ill.: We owe a responsibility to our patients, and I feel free to treat my clientele in the same manner in which our dentists treat theirs. To all women over the age of 40 for whom I have been responsible once or twice either in an obstetric manner or otherwise I send a notice every six months reminding them that they are due for a pelvic examination. This is done with their consent only and after a personal interview at their last visit in the office. In that manner we shall better serve our clientele because they need just that much reminder that they must allow us to visualize the cervix every so often during the period when it is apt to produce a carcinoma. I would stress what Dr. Novak has said about the Schiller test, and that is that it is only an aid, but it is a very good aid and we as gynecologists should use it routinely.

DR. E. H. KLOMAN, Baltimore: The few words I add will not make me popular with the general surgeon who insists on doing gynecologic operations. If the general surgeon is going to do this special line of work, he might fit himself better and be completely efficient in handling cases of cancer of the uterus. Men doing general surgery do amputations of the cervix and supravaginal hysterectomies when other operations might be indicated. They fail to do biopsies and sometimes do not seem to realize that radium is better than surgery in cancer of the cervix. I do not say this in a spirit of severe criticism, but all of us see cancers treated by the general surgeon that might have been handled in a manner greatly to the patient's advantage if the particular man had better knowledge of gynecologic conditions.

THE INFLUENCE OF RADIATION ON LONGEVITY IN CANCER OF THE BREAST

ORVILLE N. MELAND, M.D.

LOS ANGELES

In this paper I am presenting my experiences relative to the effect of radiation used alone or with surgery in cancer of the breast over a twelve year period from and including the years 1924 and 1935. There were 857 cases in all categories; of these, 803 have been traced—a follow-up of 94 per cent. Those patients who were not located are classed as lost but are not deducted; nor have deductions been made for those dying of intercurrent disease, as there is no way of ascertaining whether they might not have died of cancer had they lived.

Since the Los Angeles Tumor Institute was originally a radiologic clinic, a preponderance of the patients in the early years were treated radiologically. Open incisional biopsy was frowned on and aspiration biopsy had not been perfected, so that diagnosis was based on clinical observations. When a fixed tumor is present or where cutaneous attachment and ulceration are associated with enlarged axillary and supraclavicular nodes, the diagnosis is not in doubt, but when only a small movable lump is found in a woman less than 40 there may be an error in from 15 to 25 per cent of diagnoses made, as Pack¹ points out. However, some patients with minimum manifestations were traced for ten or more years to death, and the clinical diagnosis was verified by the presence of visceral and bony metastasis.

From the Los Angeles Tumor Institute.
Read before the Section on Radiology at the Ninety-Second Annual Session of the American Medical Association, Cleveland, June 6, 1941.

The technic and dosage of radiation changed much in the twelve year period. What was considered adequate in the early years, when little was known about tissue dosage, protraction and timing, is now known to be greatly below requirements for complete destruction of the cells. In the preoperative group the factors

TABLE 1.—Group 1: Operable (Sixty-Three Patients)

* Under type of treatment in the tables XO indicates preoperative roentgen therapy and operation; NN, roentgen therapy and radium needles interstitially, and X, roentgen therapy alone.

were as follows: 200 kilovolts, 4 milliamperes, 0.5 mm. of copper + 1 mm. of aluminum, 50 cm. distance, with a treatment time of thirty minutes daily to one area only. The areas treated were the breast, the axilla and the supraclavicular region. According to our present measurements, the dose to each area was 300 roentgens at a sitting, and since each one was treated three or four times the total dose was 900 to 1,200 roentgens, which resulted in well defined erythema and tanning. The patients going to operation were operated on in six weeks, while those treated radiologically had the treatment repeated two or three times at intervals of three months. The present procedure is to give 1,600 to 2,000 roentgens, measured in air, over each of four areas; two to the breast tangentially, one in the axilla and another over the supraclavicular region; each area is given 100 roentgens daily. The treatment is completed in about three weeks. After a waiting period of from eight to twelve weeks, when the reaction has subsided, a radical mastectomy is undertaken. This allows the full radiation effect to take place and permits primary healing in the majority of patients. The operation is done with the diathermy knife. Patients who are not to be operated on may have more radiation later, if needed, but the dosage administered is based on individual requirements.

In the postoperative series, the technic over the axilla and supraclavicular areas is the same as in the preoperative group, with a dosage of 900 to 1,200 roentgens for each area. Over the operative field low voltage

† 25 (47%) free from cancer.

is given, since there is no need for any deep seated effects. The factors are as follows: 100 kilovolts, 5 milliamperes, 0.25 mm. of copper + 1 mm. of aluminum, 30 cm. distance. The operative field is divided into different areas and one area is treated daily. It receives 350 roentgens, which is repeated in four days, for a total

of 700 roentgens, resulting in well defined erythema and tanning. This is repeated in from four to six weeks.

The technic used in interstitial irradiation is that given by Keynes² and has been described by me³ elsewhere.

CLASSIFICATION OF GROUPS

The patients treated were divided into the following groups:

Group 1. Operable (63 cases). Tumor movable, with or without cutaneous attachment; no nodes.

Group 2. Operable. Two classes (120 cases): (a) Tumor movable, with or without cutaneous attachment; slight ulceration at times; nodes low in axilla. (b) Tumor movable or partly fixed; cutaneous attachment; may be ulcerating; nodes large or small high in axilla; suspicious fullness and thickness in the supraclavicular region. This is a questionable operable class.

Group 3. Inoperable (152 cases). Tumor small or large, with or without cutaneous or fascial fixation and ulceration; nodes in axilla, supraclavicular region and/or distant metastasis.

Group 4. Postoperative recurrence (259 cases).

Group 5. Postoperative prophylactic irradiation (263 cases).

GROUP 1: OPERABLE

Although group 1 is small, it reveals the fact that the survival rate for the patients treated by preoperative radiation and interstitial radiation is the same. The rate, however, is less than the conventional rate of

TABLE 3.—Group 3: Inoperable (One Hundred and Fifty-Two Patients)

Type of Treatment	Total Patients	Lost	Dead Before 5 Years	Lived 5 Years or Longer
NN	19	1	17	1 (5%)
X	133	8	114	11 (8%)
	152	9	131	12 (9%)

70 to 75 per cent when surgery alone is used. However, 4 of the patients, who later had radical mastectomy, began treatment with the intention of avoiding surgery and waited six to eighteen months before this was done; by this time they already had nodes in the axilla. These cases are left in group 1, as the aim of the study is to see what effect radiation therapy has on permanent recovery. It is known now that whatever benefit accrues from preoperative irradiation is lost if the time between treatment and operation is unduly prolonged.

The survival rate of those treated by roentgen rays alone, being only 46 per cent, is greatly less than that of those treated surgically. Therefore, the necessity for operation in this favorable group should always be stressed. Should there be a contraindication to operation, the use of interstitial radiation should be considered as preferable to roentgen rays alone. It is further emphasized by a follow-up beyond the fifth year that permanence of recovery is maintained to a greater extent in the surgically treated group.

GROUP 2: OPERABLE

The figures in table 2 speak for themselves. The extent of the disease determines the outcome. The *a* patients have a recovery rate approaching those in group 1, and this is maintained up to the tenth year, but in the *b* patients the rate is much lower with

2. Keynes, Geoffrey: The Place of Radium in the Treatment of Cancer of the Breast, *Ann. Surg.* 106: 619-630 (Oct.) 1937.

3. Meland, O. N.: The Place of Interstitial Irradiation in Cancer of the Breast, *Am. J. Roentgenol.* 25: 348-358 (March) 1936.

5 dying from cancer after the fifth year. The combined survival rate is 54 per cent. Survival of the needled patients is about the same as that of those having mastectomy, but here the rate is not maintained, as 5 died of cancer up to the eighth year. The patients receiving only roentgen therapy had a survival rate of 25 per cent, with half of the patients dying from cancer before the tenth year. Taking 30 per cent as the accepted five year rate for the surgically treated patients in this group and comparing it to the 47 per cent who were clinically free from cancer, it is our belief that irradiation has increased the rate of survival materially.

GROUP 3: INOPERABLE

No one but the radiologists say anything about patients falling in group 3; still in this series they are almost as numerous as patients falling into the two favorable groups combined. None of these patients were operated on but were treated by radiation only. Under roentgen therapy alone the survival rate was 8 per cent. I do not say that the patients who have survived are free from cancer, but some are without clinical evidence of disease. They are comfortable and able to lead a useful existence. Of those patients treated with interstitial radiation only, 1 of 19 survived five years. Therefore, in this frankly inoperable group roentgen therapy alone disturbs the patient less and gives a greater chance of longevity.

TABLE 4.—Group 4: Postoperative Recurrent (Two Hundred and Fifty-Nine Patients)

Total Patients	Lost	Dead Before 5 Years	Lived 5 Years or Longer
259	11	220	28 (11%)

GROUP 4: POSTOPERATIVE RECURRENT

In group 4 again are patients in whom the radiologist is much interested, since the group is made up of surgical failures. It represents the end of the road and most often it falls to the radiologist to make the patients mentally and physically comfortable. The results of treatment are given in table 4.

As a result of careful radiation therapy, 28, or 11 per cent, have lived from five to fifteen years after therapy was begun. This represents a salvage obtained in which 88 per cent of the recurrences took place in the first four years after operation. However, 3 per cent of the recurrences took place in patients from the tenth to the twenty-seventh year after operation. It confirms the Lewis and Rienhoff⁴ contention that, no matter how favorable the case or how careful the operation, death from carcinoma may take place years after the conventional five year period of curability has passed. Following up the 28 patients beyond the five year period. I found that 2 died of intercurrent disease, 10 died of cancer from the sixth to the eleventh year after treatment, 4 are living with cancer from the sixth to the tenth year and 12 are living and well, clinically free from cancer, from the sixth to the fifteenth year.

GROUP 5: POSTOPERATIVE PROPHYLACTIC IRRADIATION

Patients falling in group 5 represent a controversial group about whom much discussion has taken place. With the exception of radiologists, who have had a great enough experience and who are in the minority,

4. Lewis, Dean, and Rienhoff, W. F., Jr.: A Study of the Results of Operation for the Care of Cancer of the Breast, *Ann. Surg.* 95: 336-400 (March) 1932.

the consensus, largely surgical, is that postoperative irradiation does not add anything to the five year end results. This view is ably presented by Harrington⁵ and Greenough.⁶ Since the records are not complete, we are unable to separate the patients into groups 1 and 2, but the combined series gives a survival rate of 39 per cent in which the patients are clinically free from cancer. Except for some of our own

TABLE 5.—Group 5: Postoperative Prophylactic Irradiation (Two Hundred and Sixty-Three Patients)

Total Patients	Lost	Dead	Five Year Survivals
263	23	138	102 (39%)

patients, this represents the effort of twenty surgeons, some of whom have had extensive experience in surgery of the breast but many of whom operate on only one or two breasts a year. Furthermore, many patients were referred to the institute with a notation on their history that a radical operation had been done, but the pectoral muscles were found to be intact. It is important for one to bear this in mind, since it represents the "average" surgical material seen in any community, when comparing it to the Mayo Clinic or the Harvard Clinic series, in which a definite fixed surgical technic is maintained. Since we have no control group of our own to compare with the groups in which no postoperative irradiation was given, it is difficult to draw any definite conclusions. Comparing our series with Bartlett's⁷ carefully worked out series, in which he obtained a five year curability of 31 per cent, our results of 39 per cent show that irradiation adds 8 per cent; or, in comparison to the table compiled by Fortmann⁸ from the world literature, in which there is a mean average five year survival of 28 per cent, postoperative irradiation in our series shows an 11 per cent improvement.

SURVIVAL RATE IN CASES IN WHICH DEATH OCCURRED WITHIN FIVE YEAR PERIOD

Before the subject is dismissed, it is interesting to see what the survival rate in months is of patients who have died from cancer within the five year period, according to the method of treatment used. Two hundred and thirteen cases fall in this category (table 6).

TABLE 6.—Survival Rate in Months in Cases of Cancer Deaths Within Five Year Period

Type of Treatment	Group 1		Group 2		Group 3	
	Cases	Survival, Months	Cases	Survival, Months	Cases	Survival, Months
X	13	40	26	23	114	14
XX	4	28	9	23	17	21
XO	7	32	23	22	0	0

These figures in table 6 refute the charge that is sometimes made that irradiation hastens the fatal outcome, for the patients receiving roentgen therapy alone lived longer than those who had either operation or
